# Deep Learning

Session 10 and 11

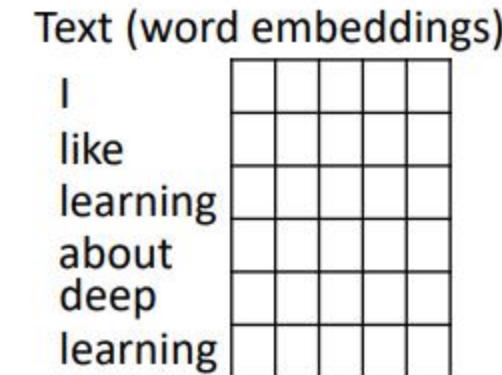

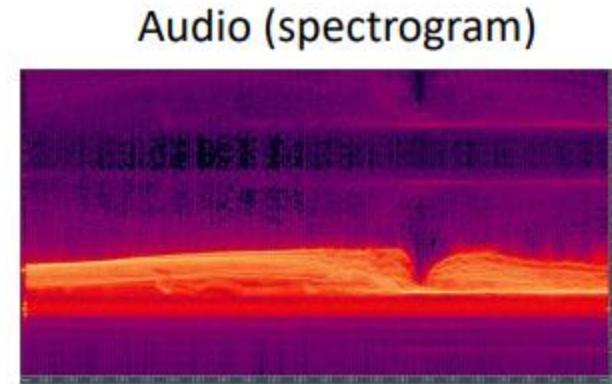

## Convolutional Neural Networks (CNNs)

Applied Data Science

2024/2025

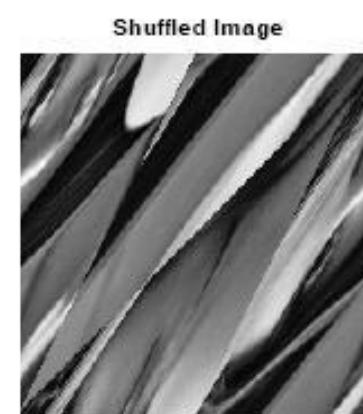

# Spatial Data

- **Definition:** Spatial data refers to data where the arrangement or location of elements is important.

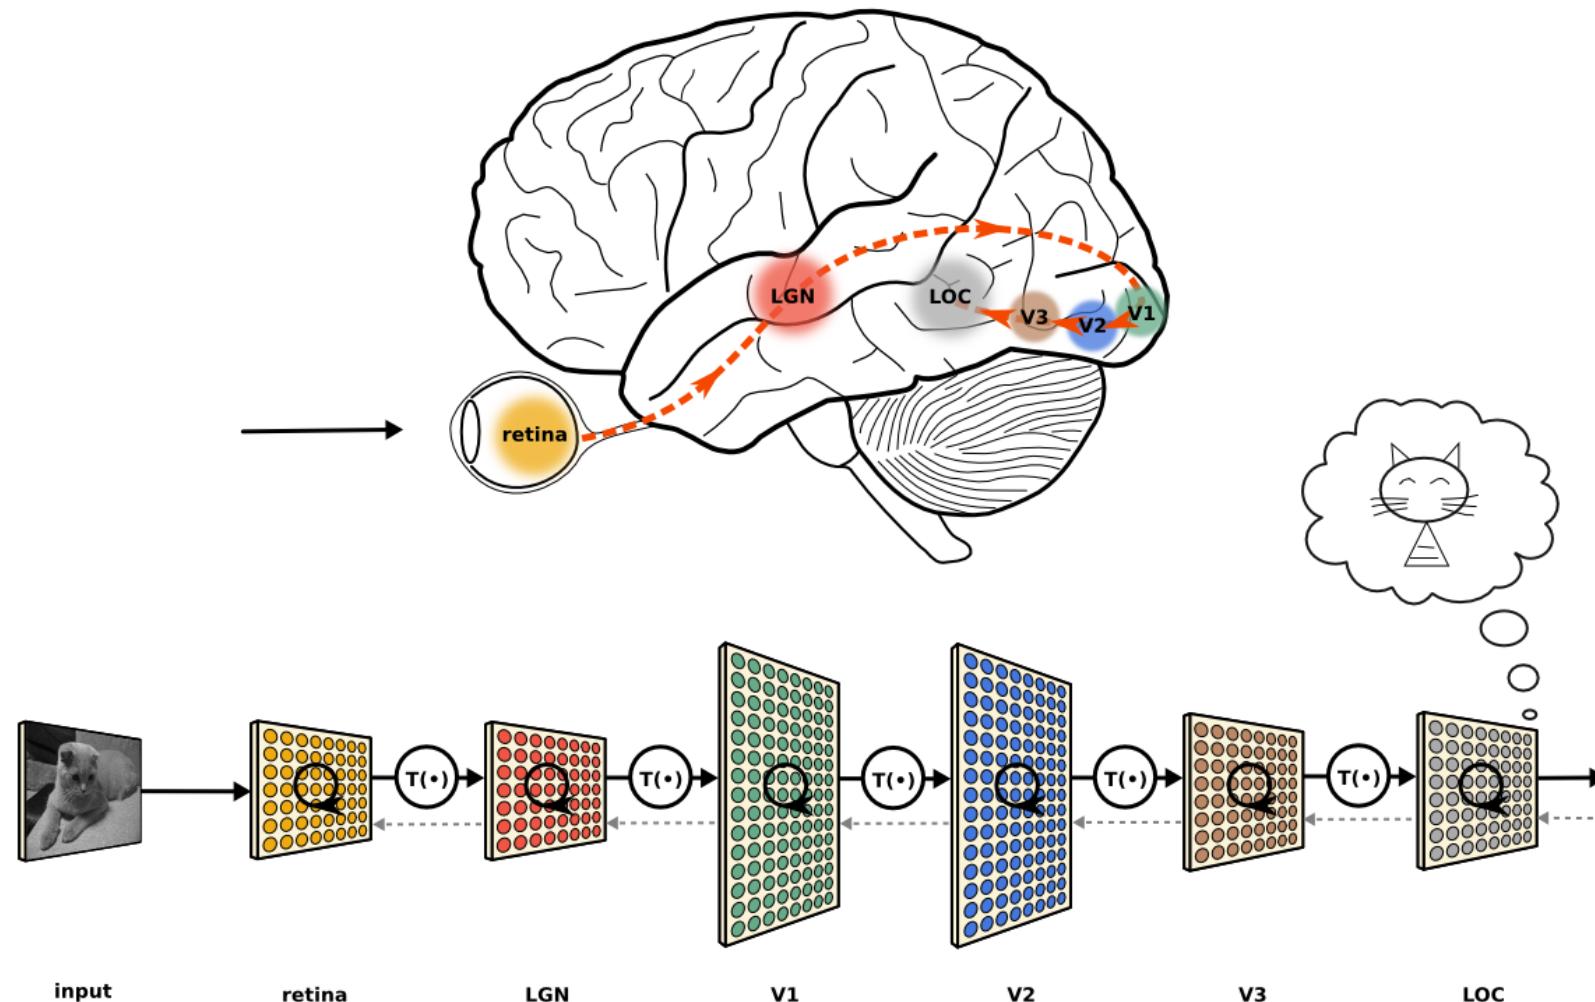

# Why Spatial Structure Matters?

- **Local Patterns:** In spatial data, nearby elements (e.g., pixels) often have strong relationships.
  - Example: Edges, textures, and objects in an image are defined by neighboring pixel values.
- **Context Preservation:** Spatial arrangement helps capture context.
  - Example: In an image, nearby pixels form features like eyes, while distant pixels represent unrelated parts (e.g., background).

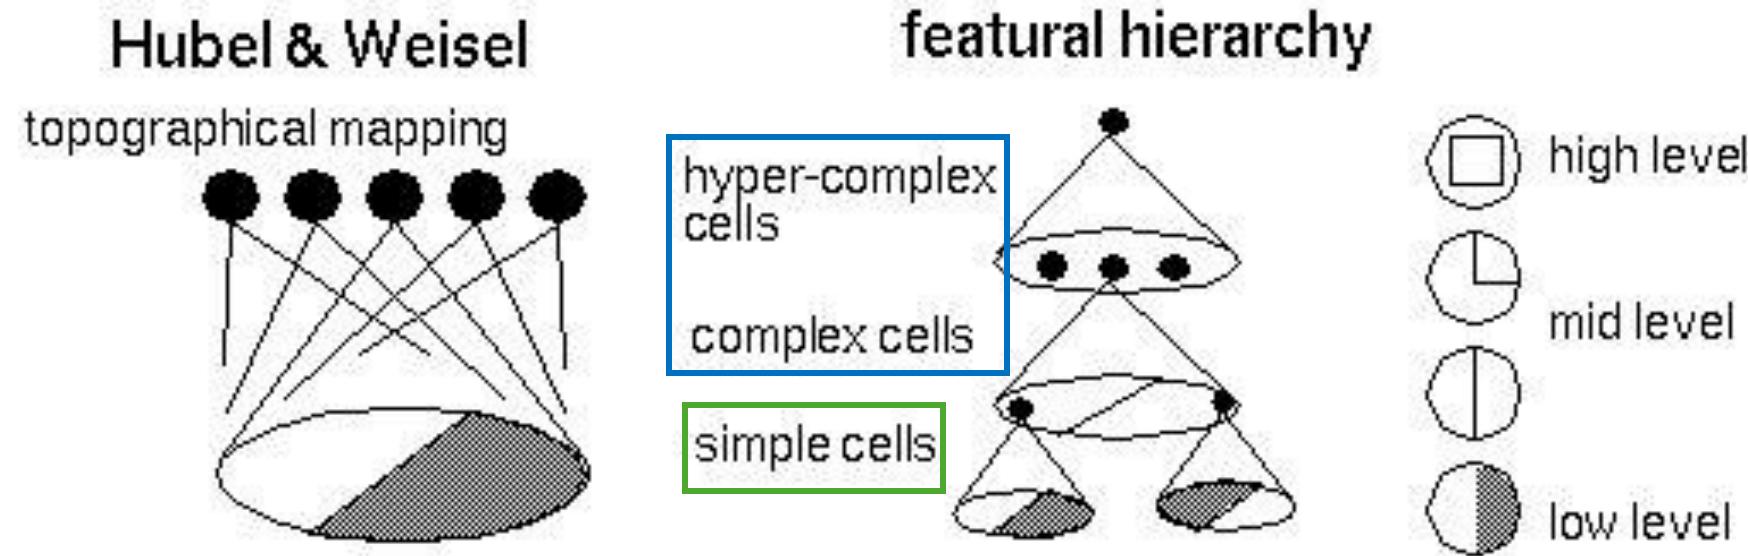

# Motivation: How Vision Systems Work

de-Wit, L. H., Kubilius, J., de Beeck, H. P. O., & Wagemans, J. (2013). Configural Gestalts Remain Nothing More Than the Sum of Their Parts in Visual Agnosia. In *i-Perception* (Vol. 4, Issue 8, pp. 493–497). SAGE Publications. <https://doi.org/10.1068/i0613rep>

# Motivation: How Vision Systems Work

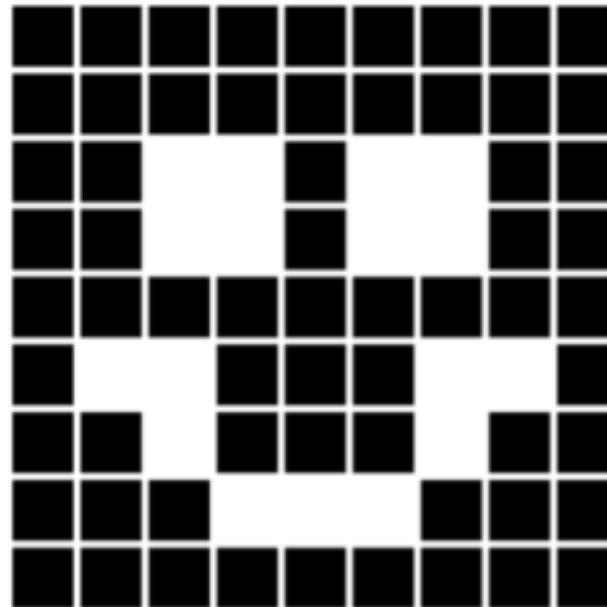

- **Key Idea:** cells are organized as a hierarchy of feature detectors, with **higher level features** responding to patterns of activation in **lower level cells**

Fukushima, 1980.

# Challenges of Fully Connected Networks

- Fully-Connected Layers are Limited

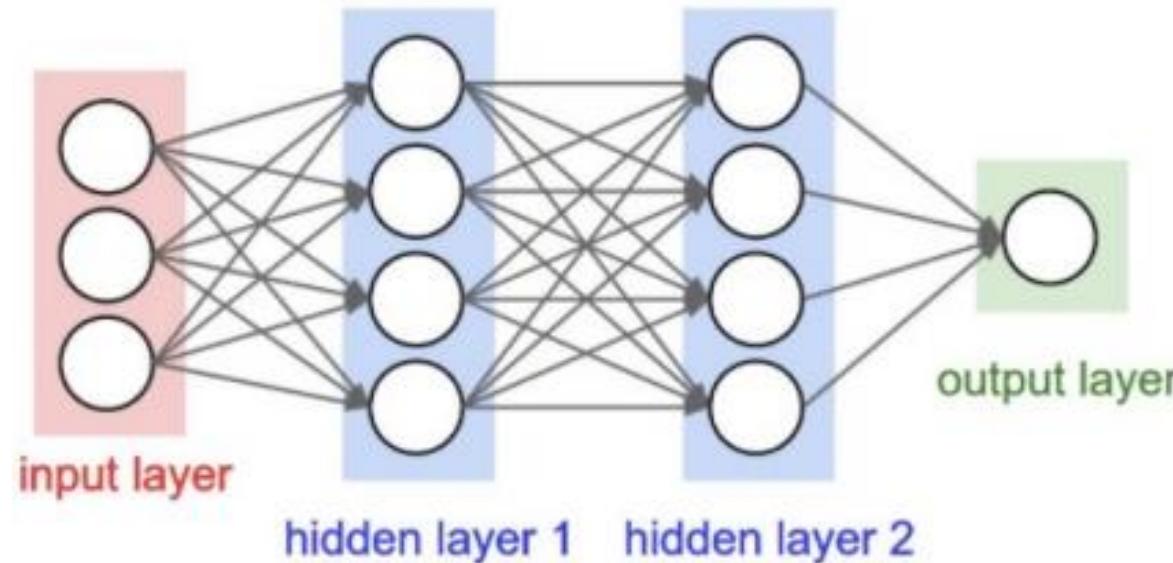

- Each node provides input to each node in the next layer.
- No spatial information!

# Challenges of Fully Connected Networks

- Assume 2 layer model with 100 nodes per layer
  - e.g., how many weights are in a colored 640x480 image?

# Challenges of Fully Connected Networks

- Assume 2 layer model with 100 nodes per layer
  - e.g., how many weights are in a colored 640x480 image?
    - $640 \times 480 \times 3 \times 100 + 100 \times 100 + 100 \times 1 = 92,170,100$
  - e.g., how many weights are in a 2048X1536 image (3.1 Megapixel image)?
    - $2048 \times 1536 \times 3 \times 100 + 100 \times 100 + 100 \times 1 = 943,728,500$

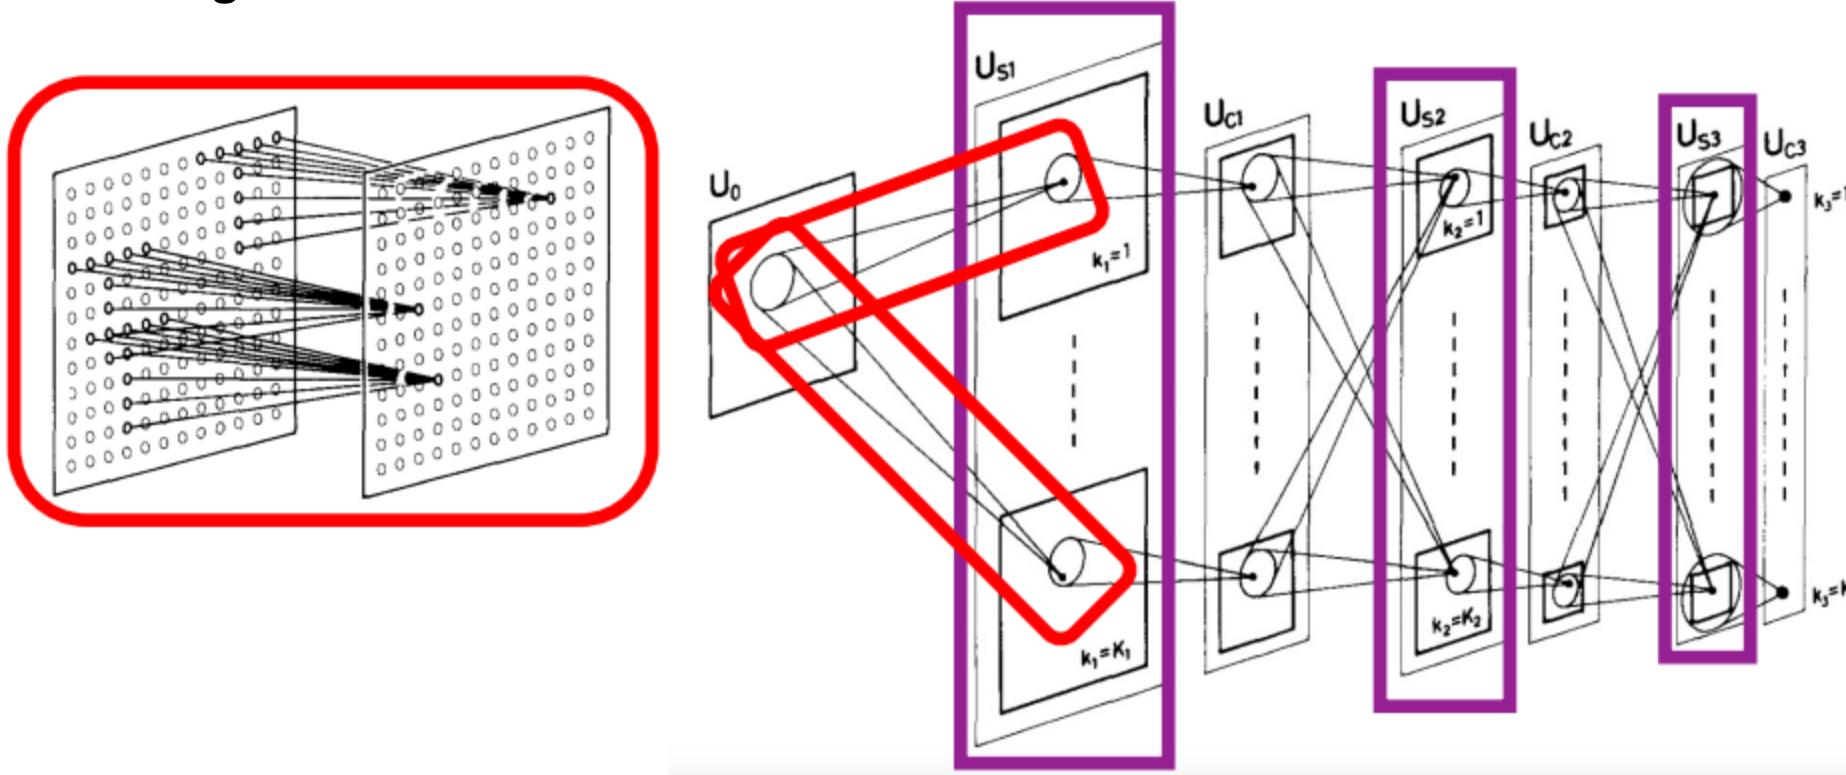

# Challenges of Fully Connected Networks

- **Issue:** many model parameters in fully connected networks
- **Many model parameters and so...**
  - Greater chance to overfit
  - Increased training time
  - Needs more training data

# Convolutional Layers

- **Idea:** each node receives input only from a small neighborhood in previous layer and parameter sharing

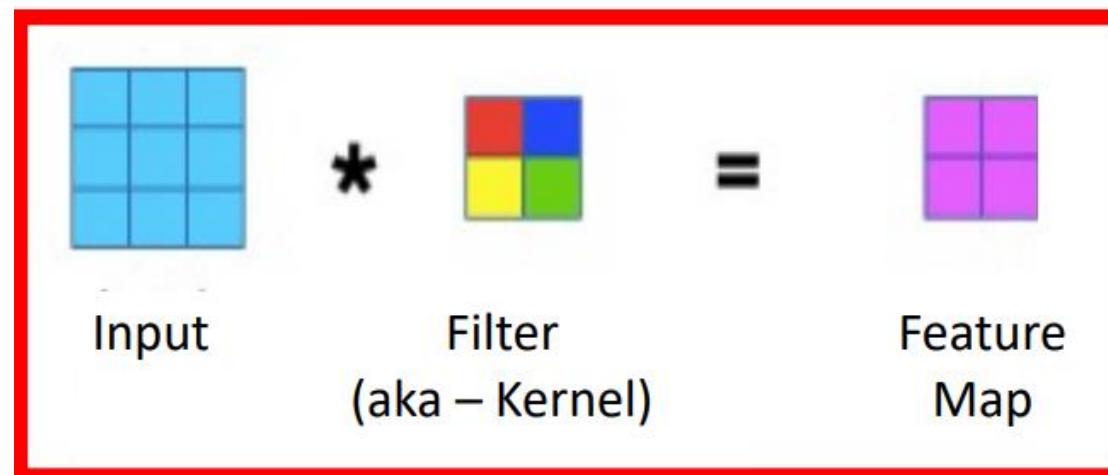

## Neocognitron

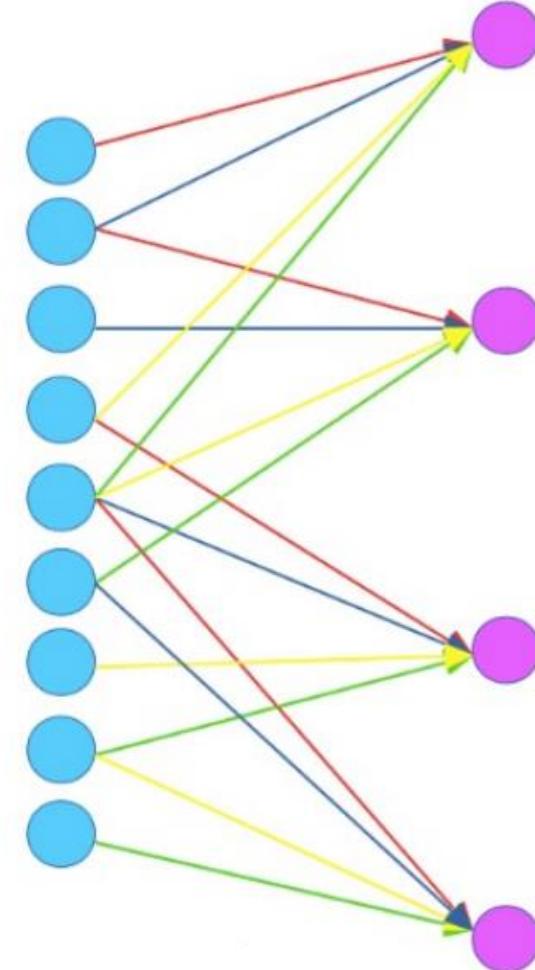

Fukushima, 1980.

# Convolution

- Applies a linear **filter** (e.g., 2D)

# Convolution

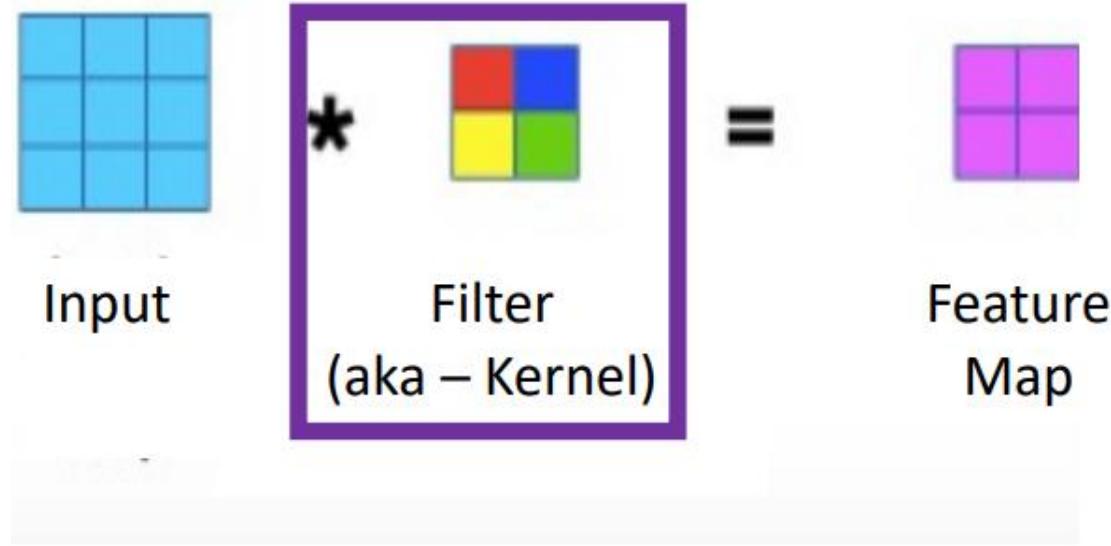

Center element of the kernel is placed over the source pixel. The source pixel is then replaced with a weighted sum of itself and nearby pixels.

# Convolutional Layer: Parameters to Learn

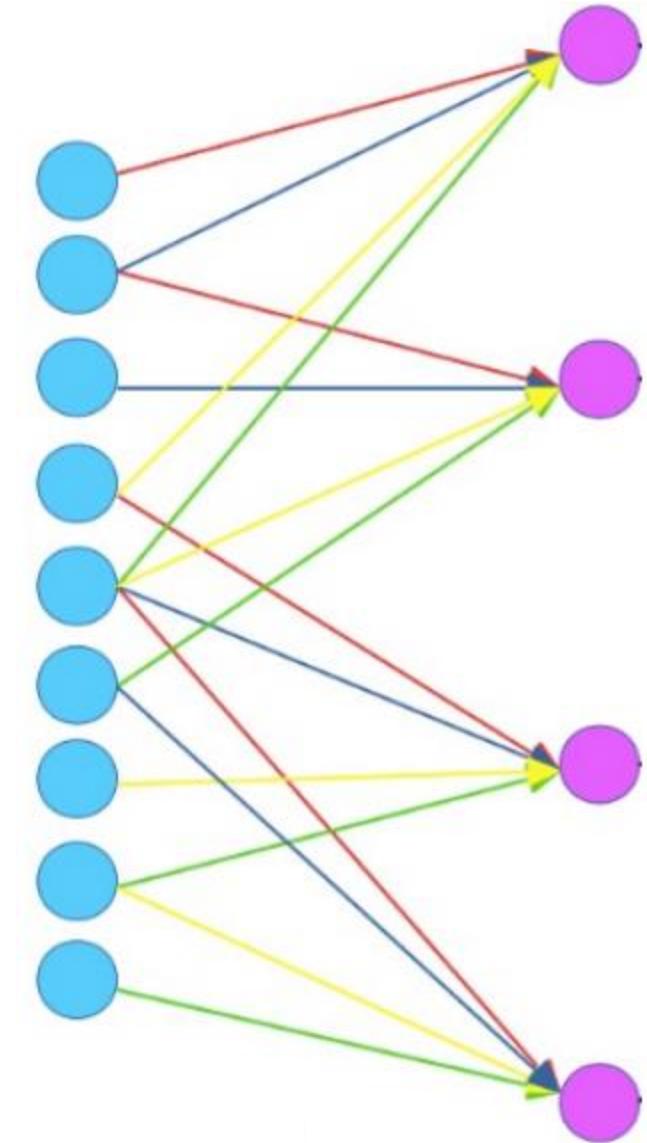

Way to Interpret  
Neural Network

<https://www.jefkine.com/general/2016/09/05/backpropagation-in-convolutional-neural-networks/>

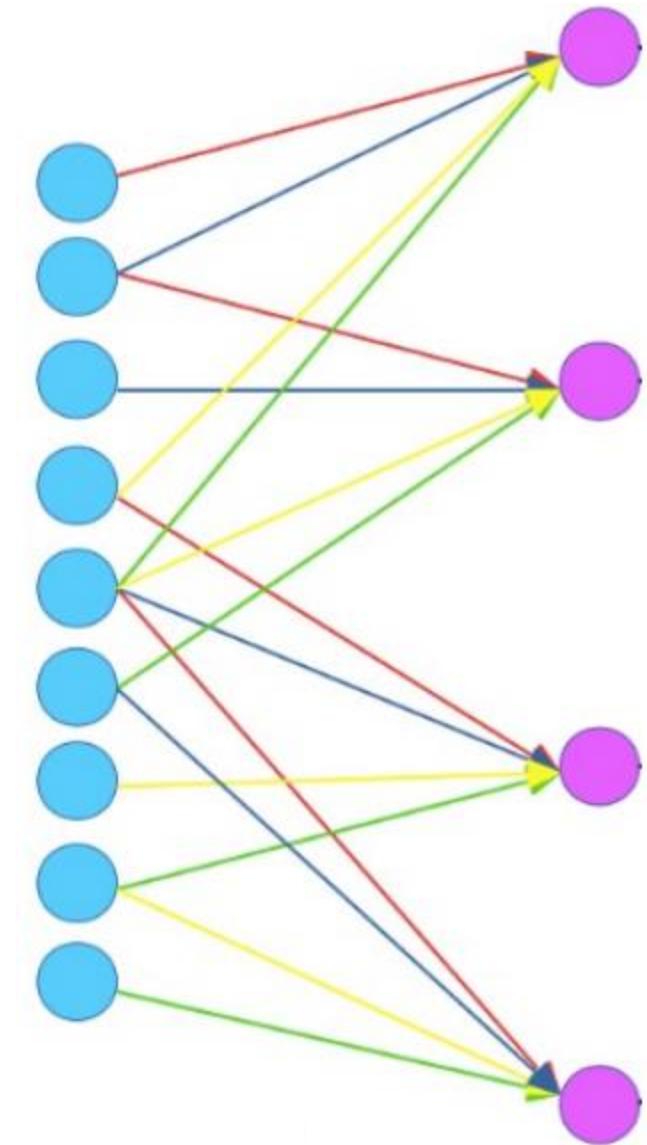

# Convolutional Layer: Parameters to Learn

- For the shown example, how many weights must be learned?

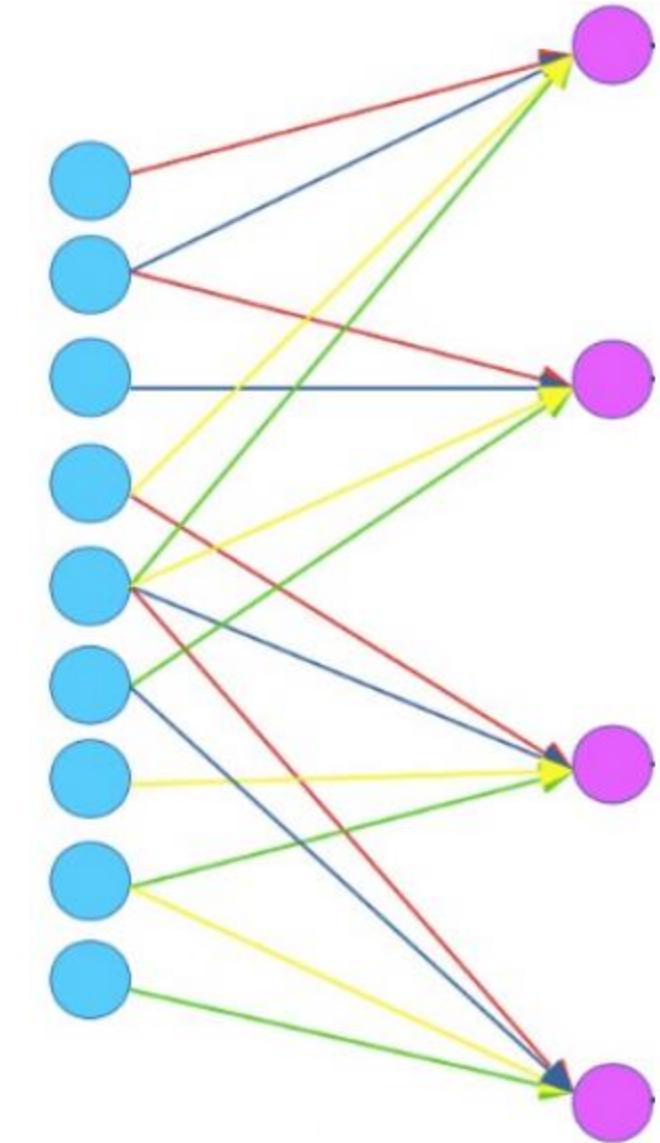

# Convolutional Layer: Parameters to Learn

- For the shown example, how many weights must be learned?
  - **4 (red, blue, yellow, and green values)**
- If we instead used a fully connected layer, how many weights would need to be learned?

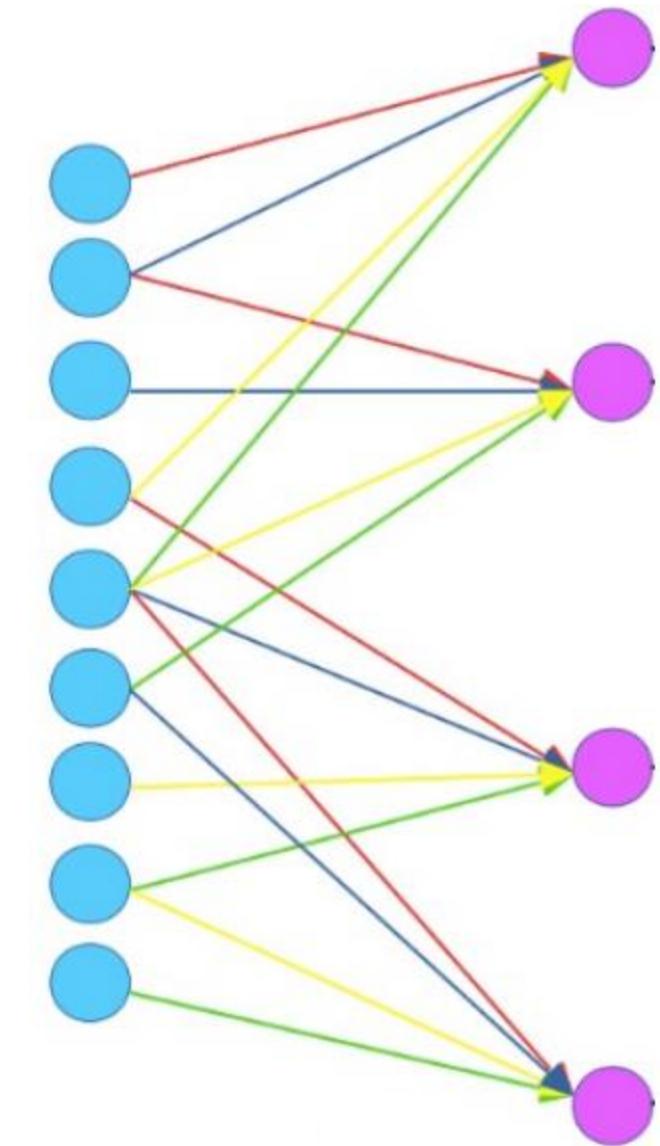

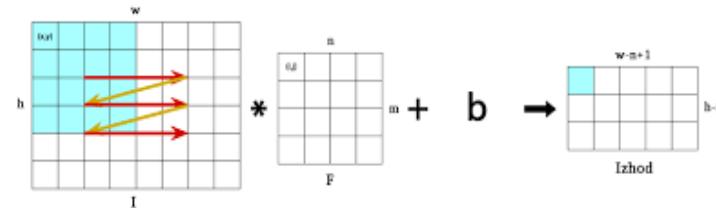

# Convolutional Layer: Parameters to Learn

- For the shown example, how many weights must be learned?
  - 4 (red, blue, yellow, and green values)
- If we instead used a fully connected layer, how many weights would need to be learned?
  - **36 (9 turquoise nodes x 4 magenta nodes)**
- For shown example, how many parameters must be learned?

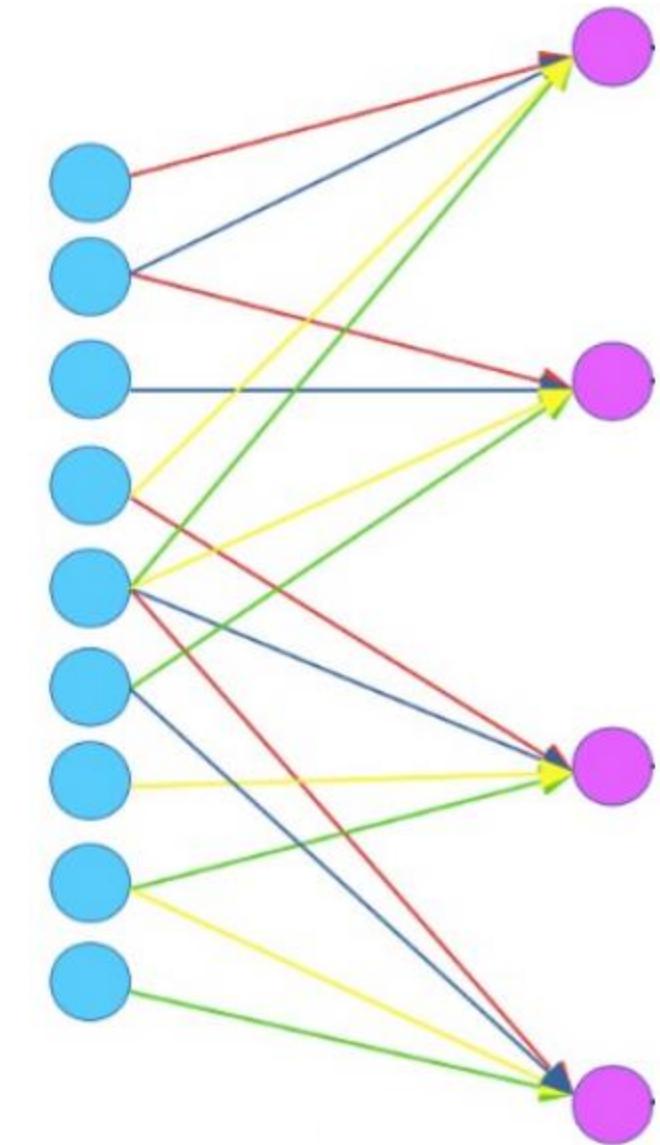

# Convolutional Layer: Parameters to Learn

- For the shown example, how many weights must be learned?
  - 4 (red, blue, yellow, and green values)
- If we instead used a fully connected layer, how many weights would need to be learned?
  - 36 (9 turquoise nodes x 4 magenta nodes)
- For the shown example, how many parameters must be learned?
  - **5 (4 weights + 1 bias)**
- If we instead used a fully connected layer, how many parameters would need to be learned?

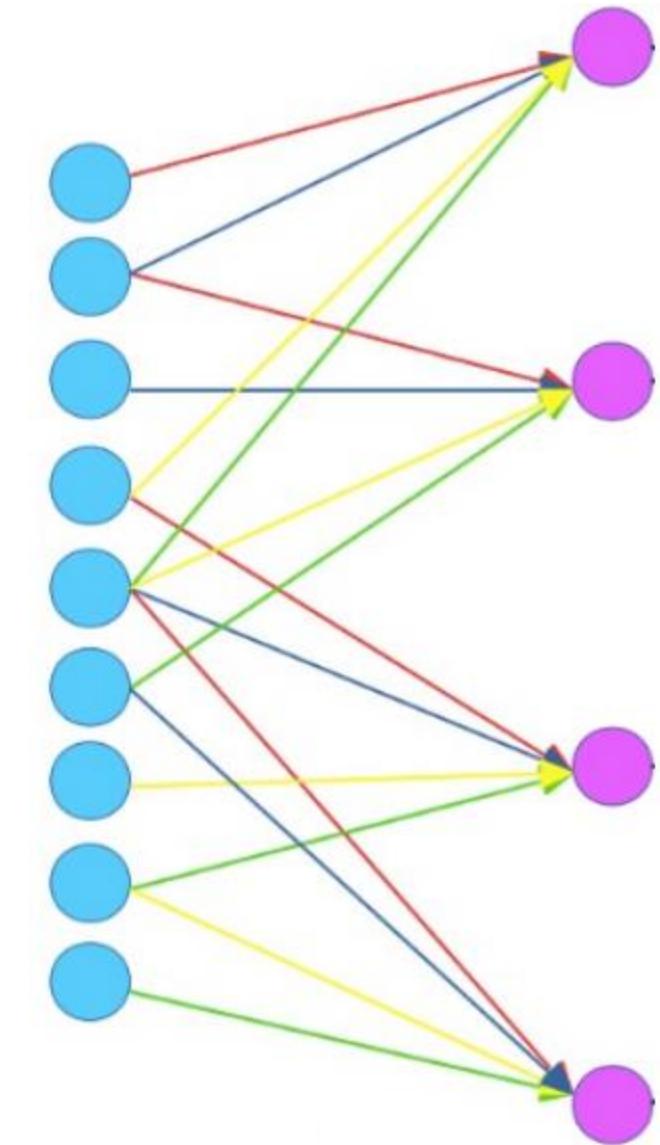

# Convolutional Layer: Parameters to Learn

- For the shown example, how many weights must be learned?
  - 4 (red, blue, yellow, and green values)
- If we instead used a fully connected layer, how many weights would need to be learned?
  - 36 (9 turquoise nodes x 4 magenta nodes)
- For the shown example, how many parameters must be learned?
  - 5 (4 weights + 1 bias)
- If we instead used a fully connected layer, how many parameters would need to be learned?
  - **40 (36 weights + 4 bias)**

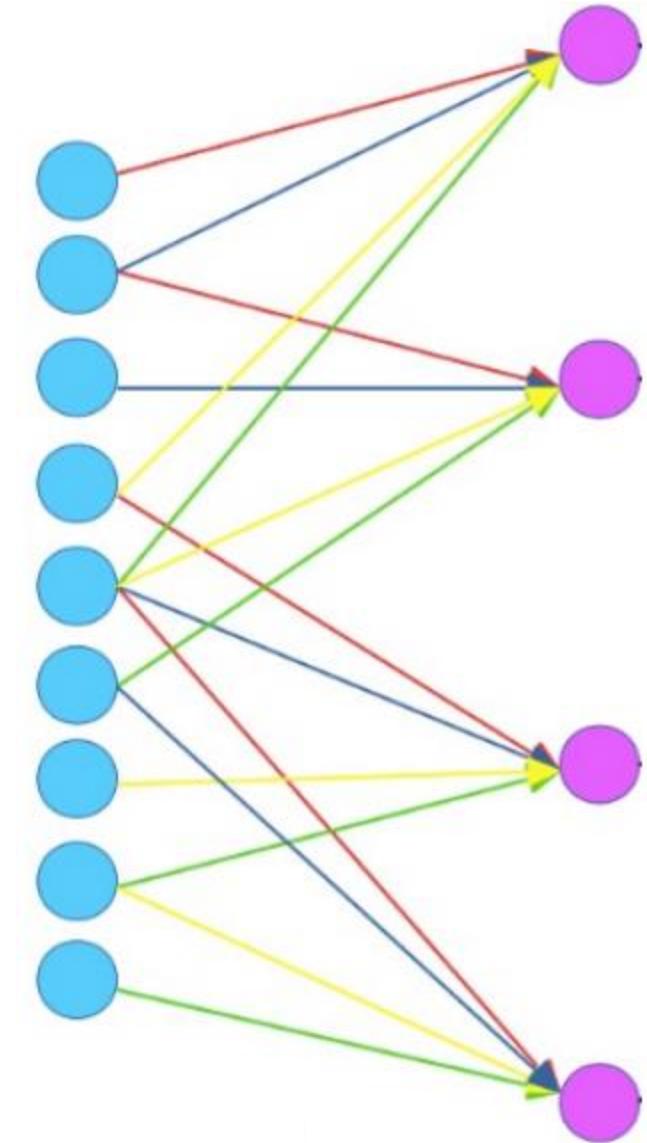

# Convolutional Layer: Parameters to Learn

- **Parameter sharing** significantly reduces number of parameters to learn and so storage requirements
- **Sparse connectivity** (rather than full) also significantly reduces the number of computational operations required

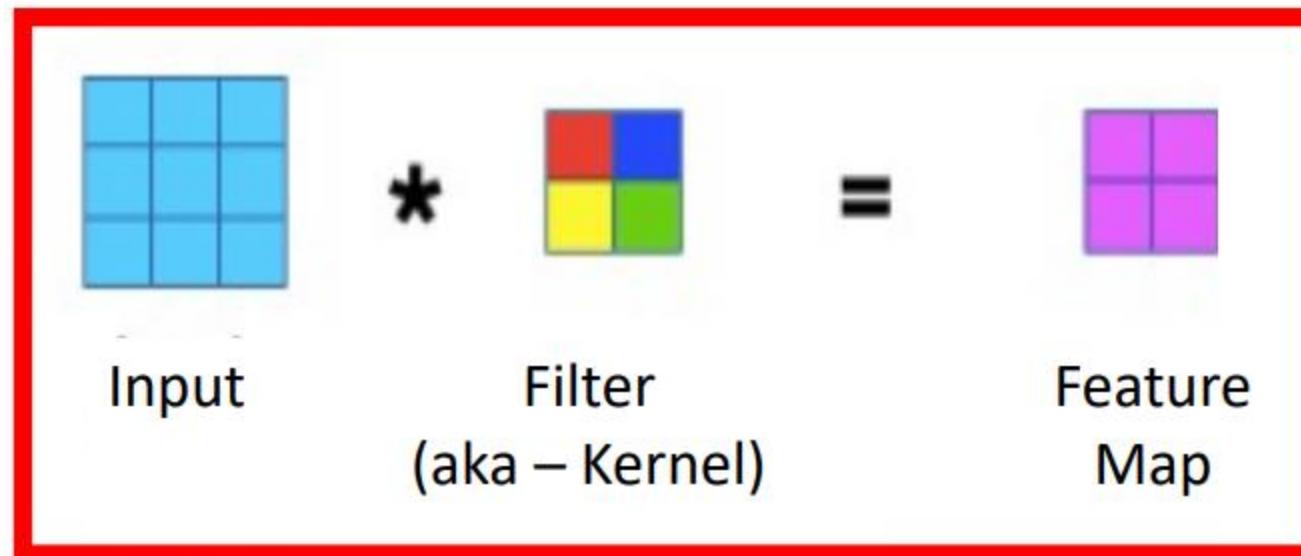

# Convolutional Layer: Parameters to Learn

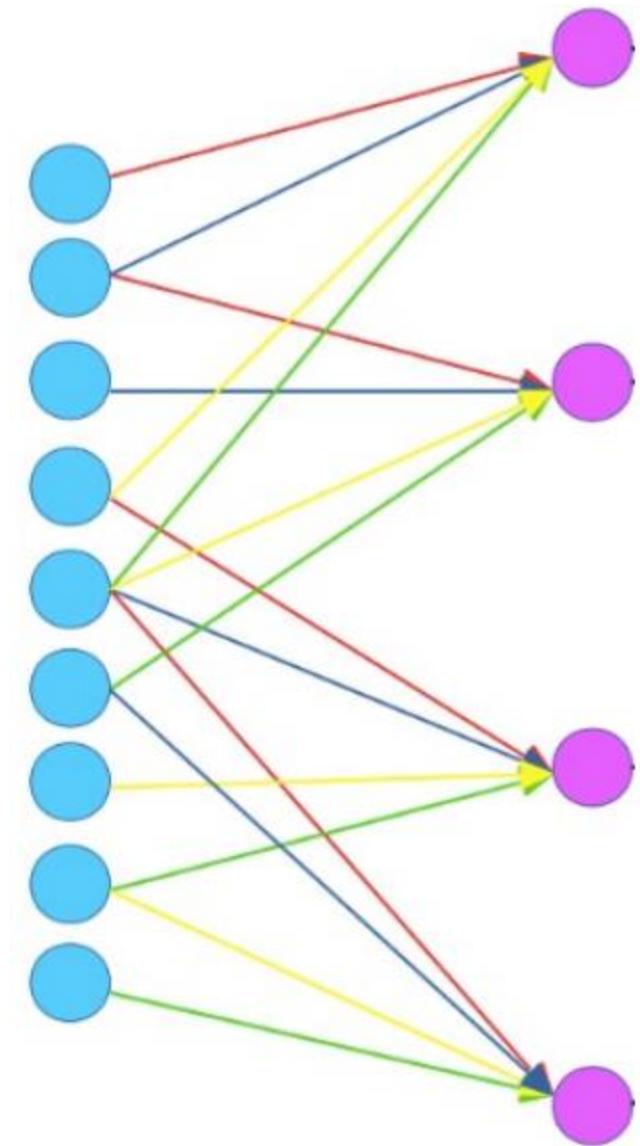

- Neocognitron has hard-coded filter values... we will cover models that learn the filter values

# Group Discussion

1. How would you design a filter to “brighten” an image?

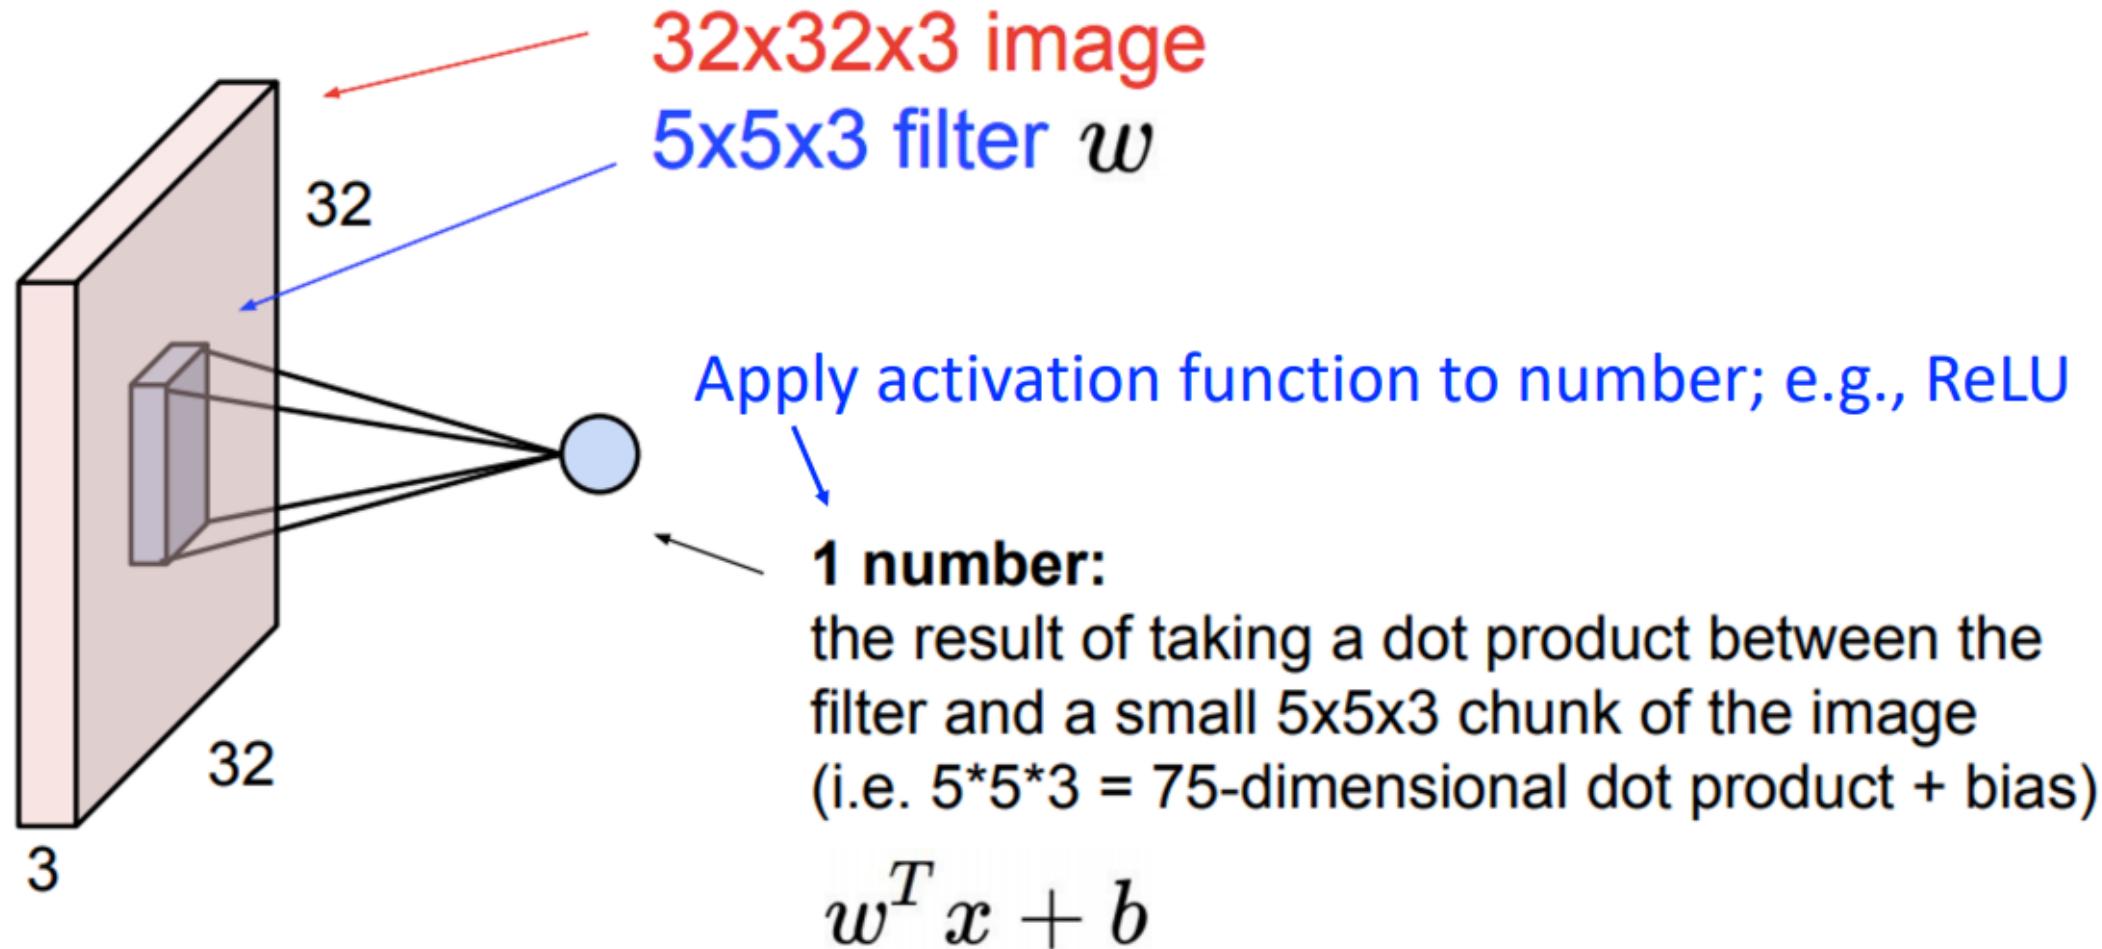

2. How would you design a filter to remove wrinkles/blemishes?

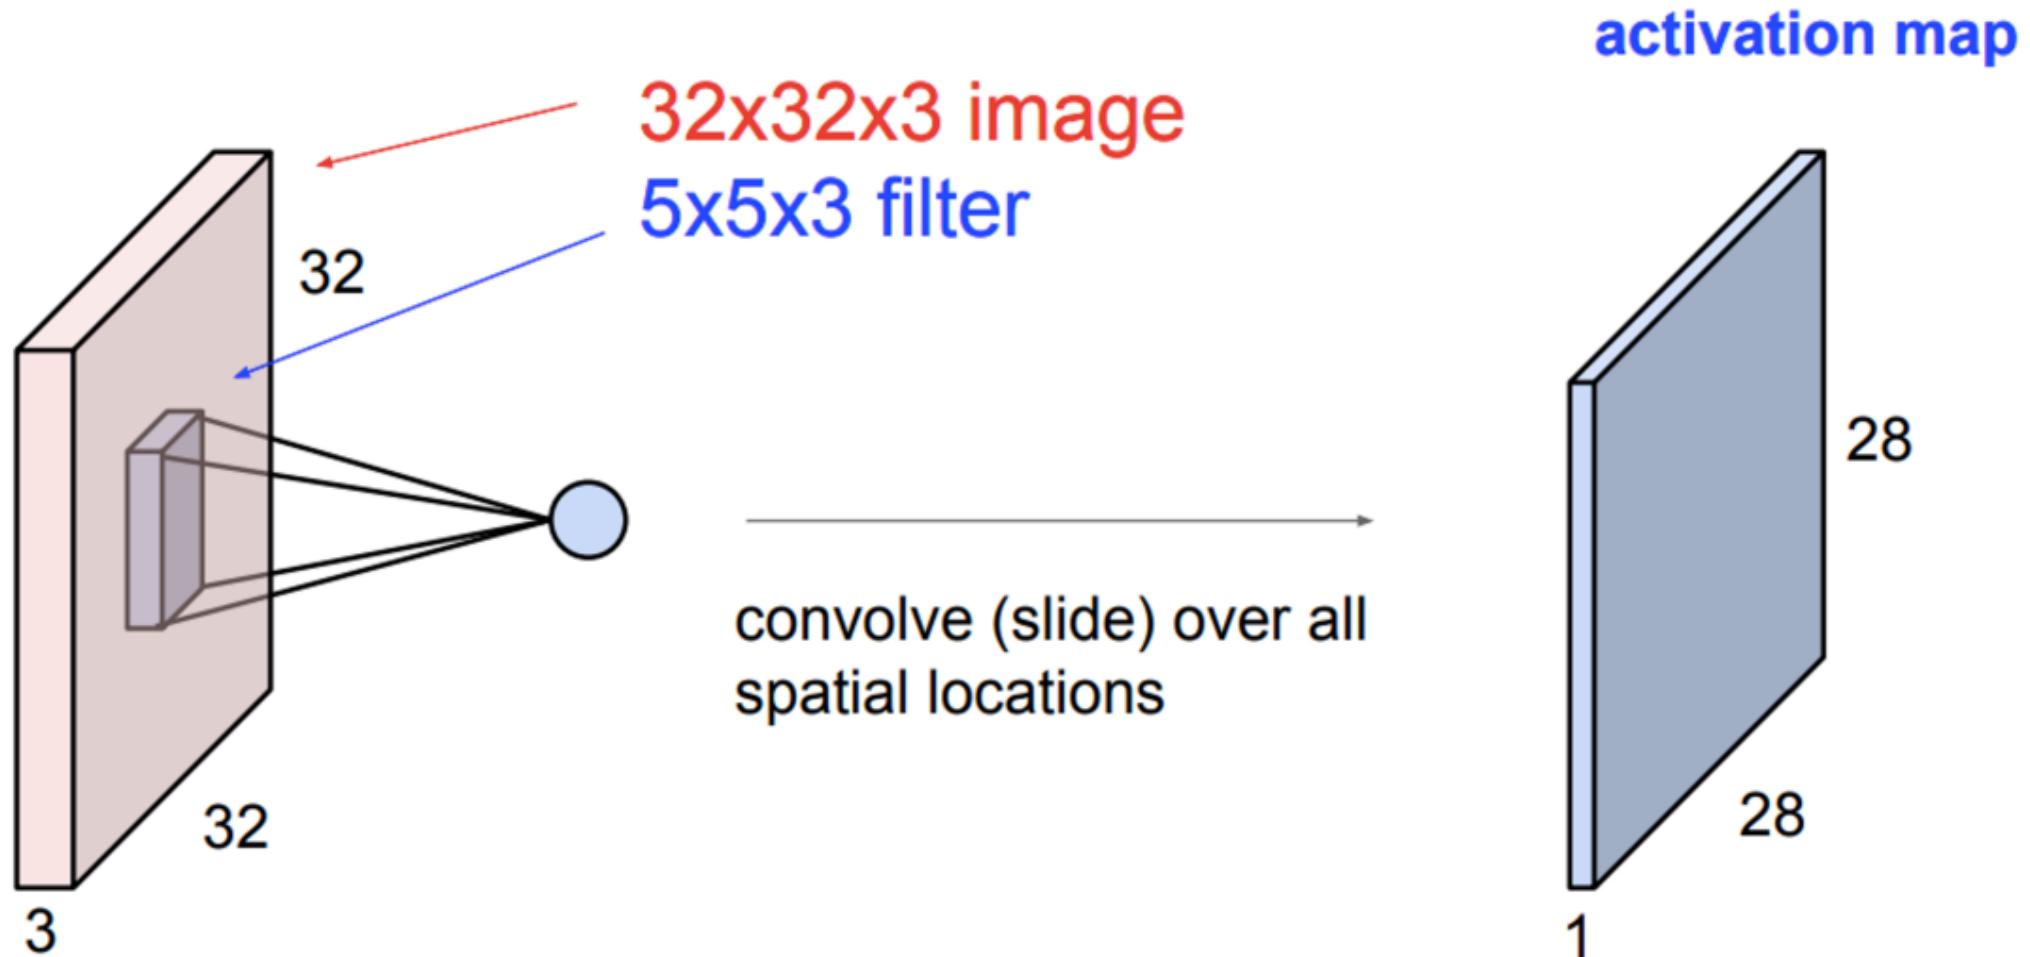

# Convolutional Layer

- After applying the filter, introduce non-linearity

# Convolutional Layer

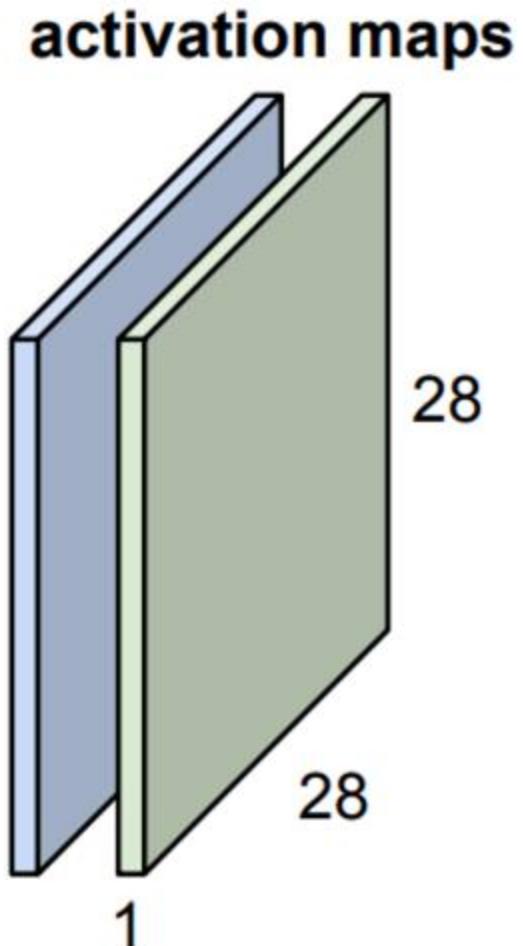

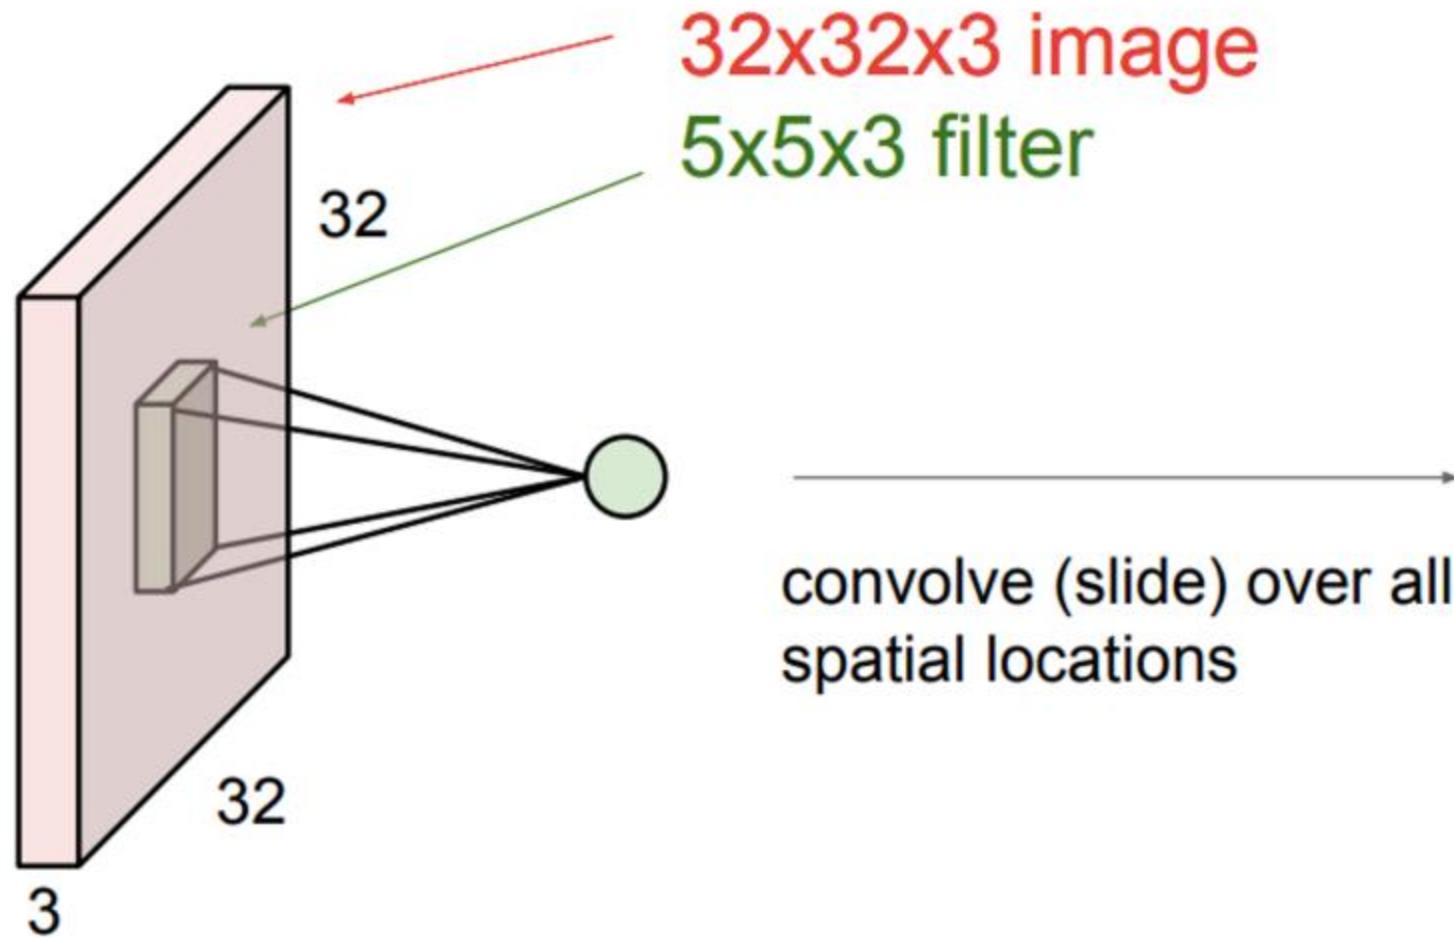

- Slide filter across input

# Convolutional Layer

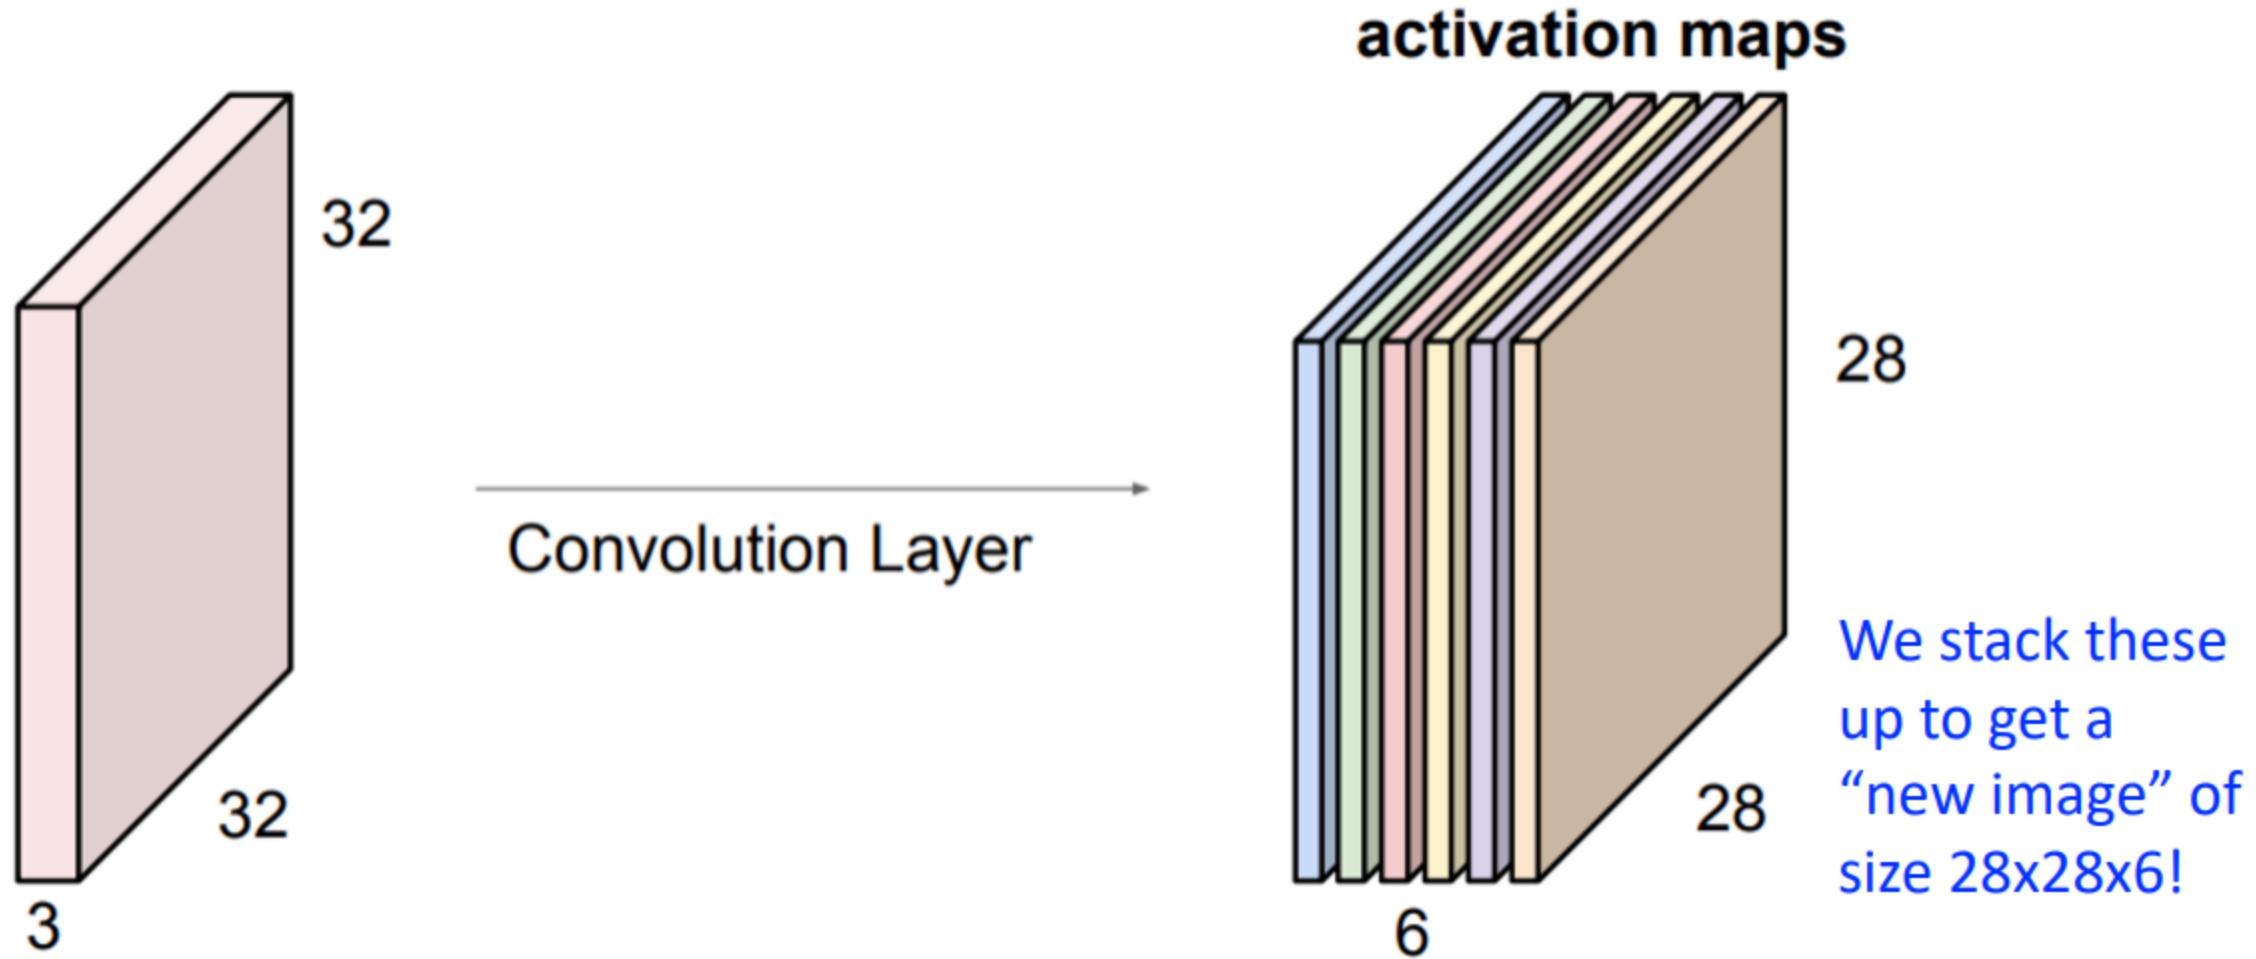

- Slide filter across input

Consider a second, green filter.

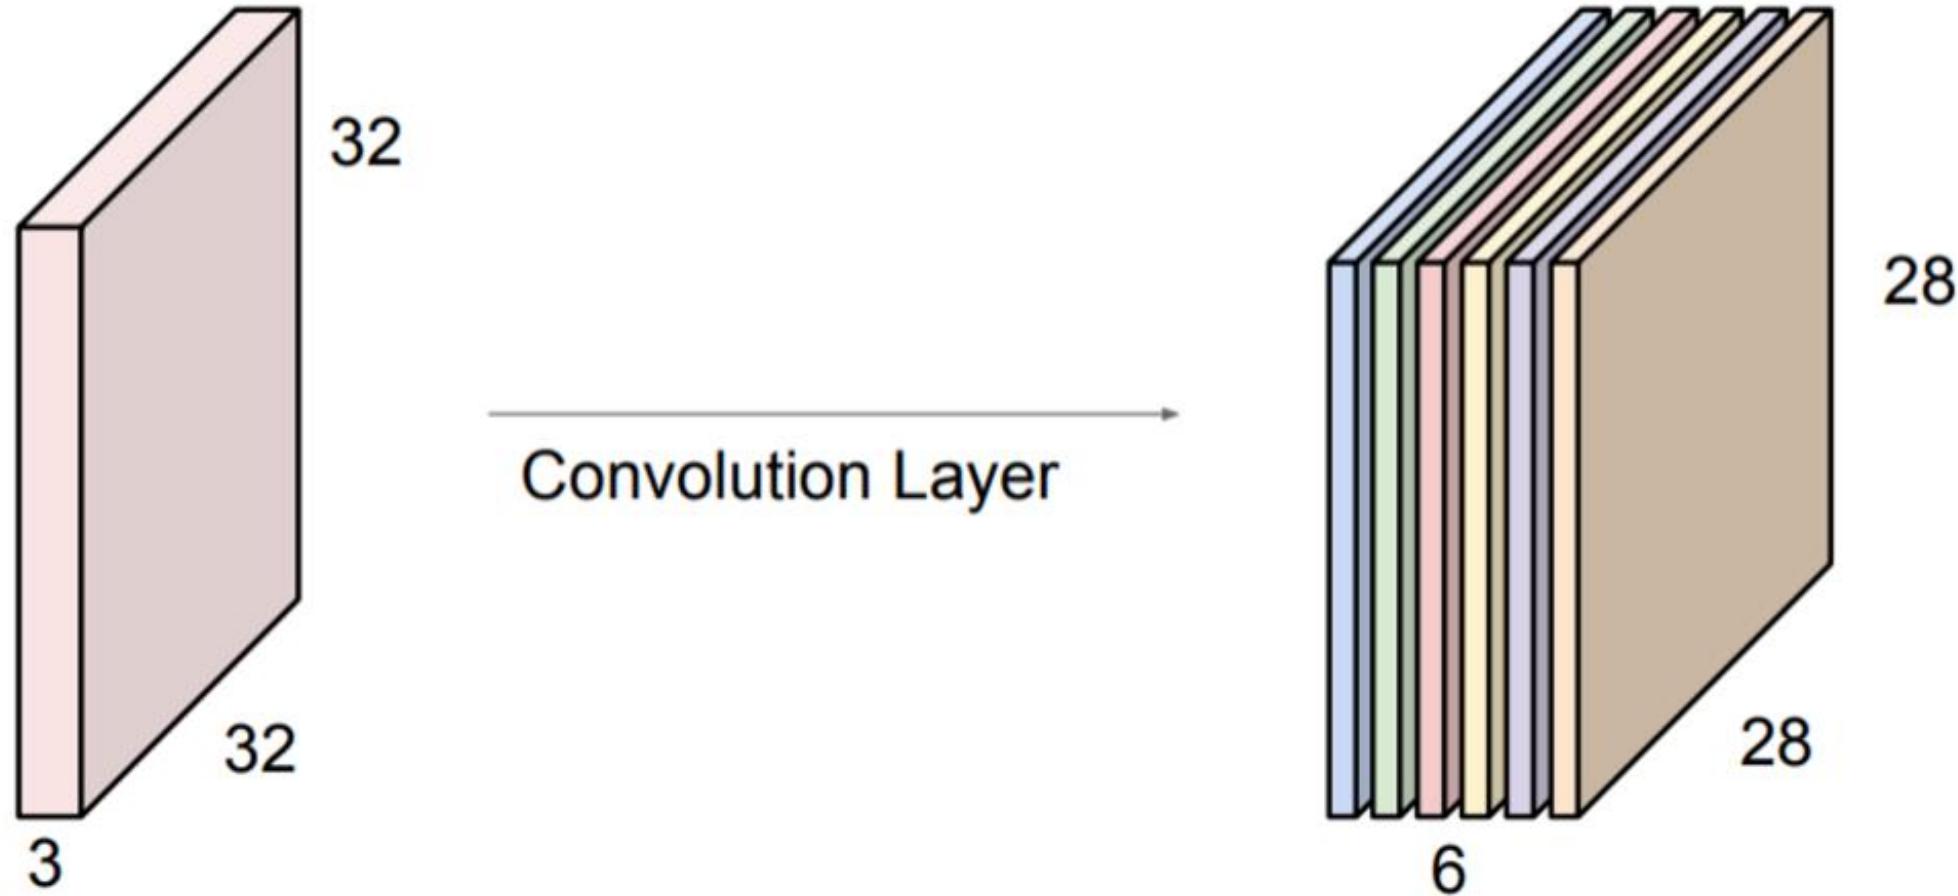

# Convolutional Layer

if we had 6 5x5 filters, we'll get 6 separate activation maps:

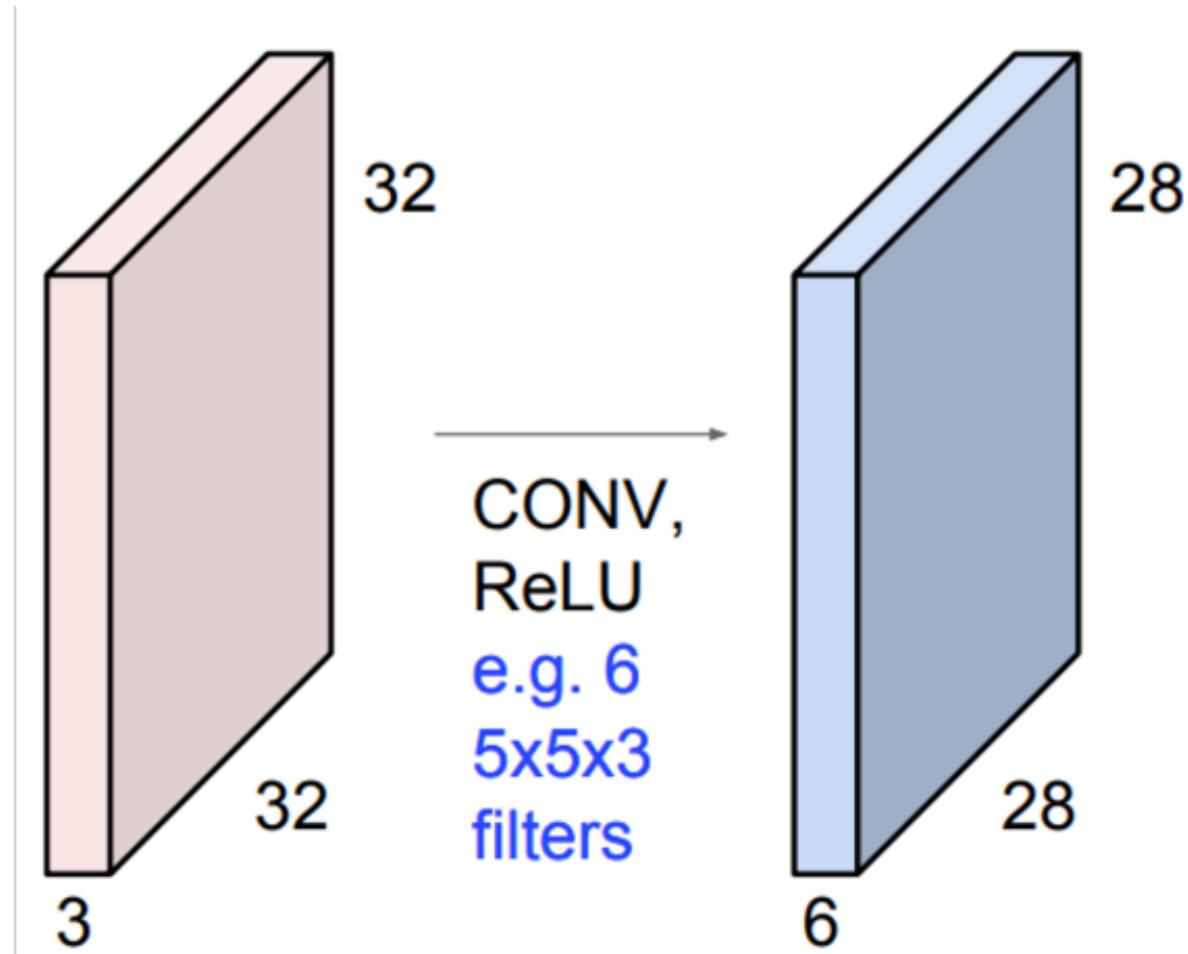

# Convolutional Layer: Parameters to Learn

Parameters: bank of filters and biases used to create the activation maps (aka – feature maps)  
**activation maps**

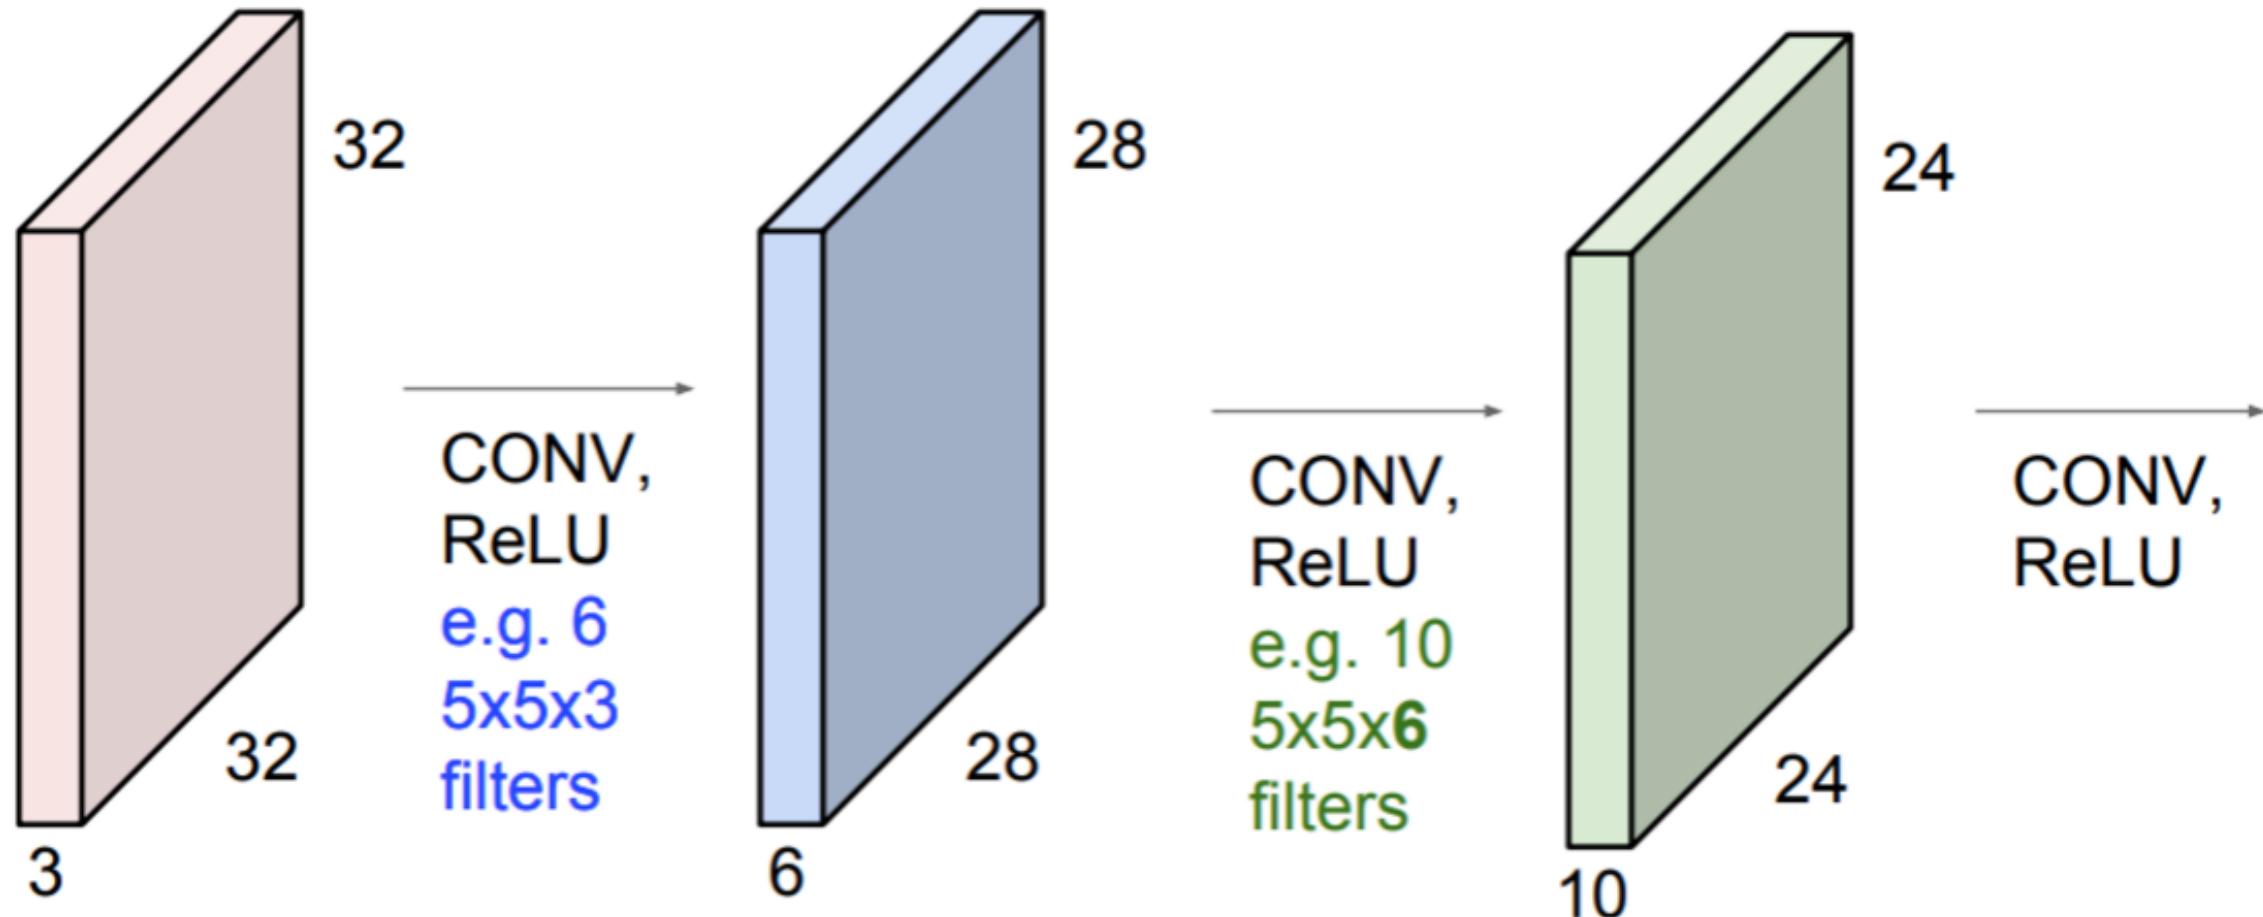

# Convolutional Layers Stacked

Can then stack a sequence of convolution layers, interspersed with activation functions:

# Convolutional Layers Stacked

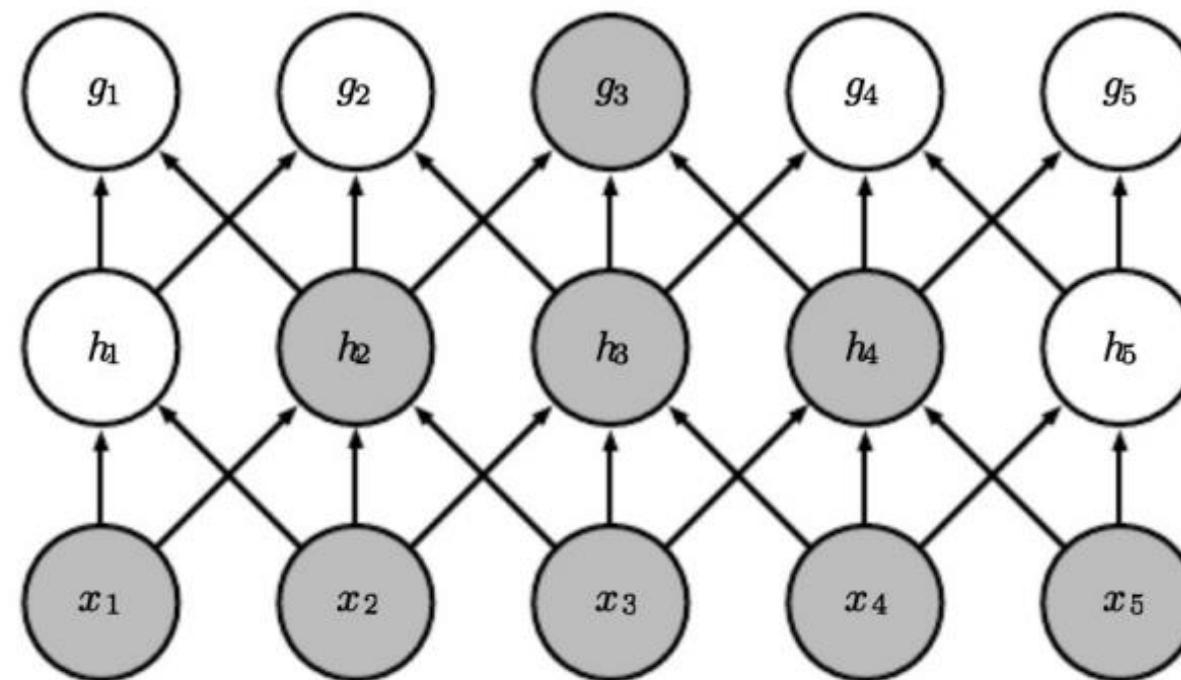

Can then stack a sequence of convolution layers, interspersed with activation functions:

# Convolutional Layers Stacked

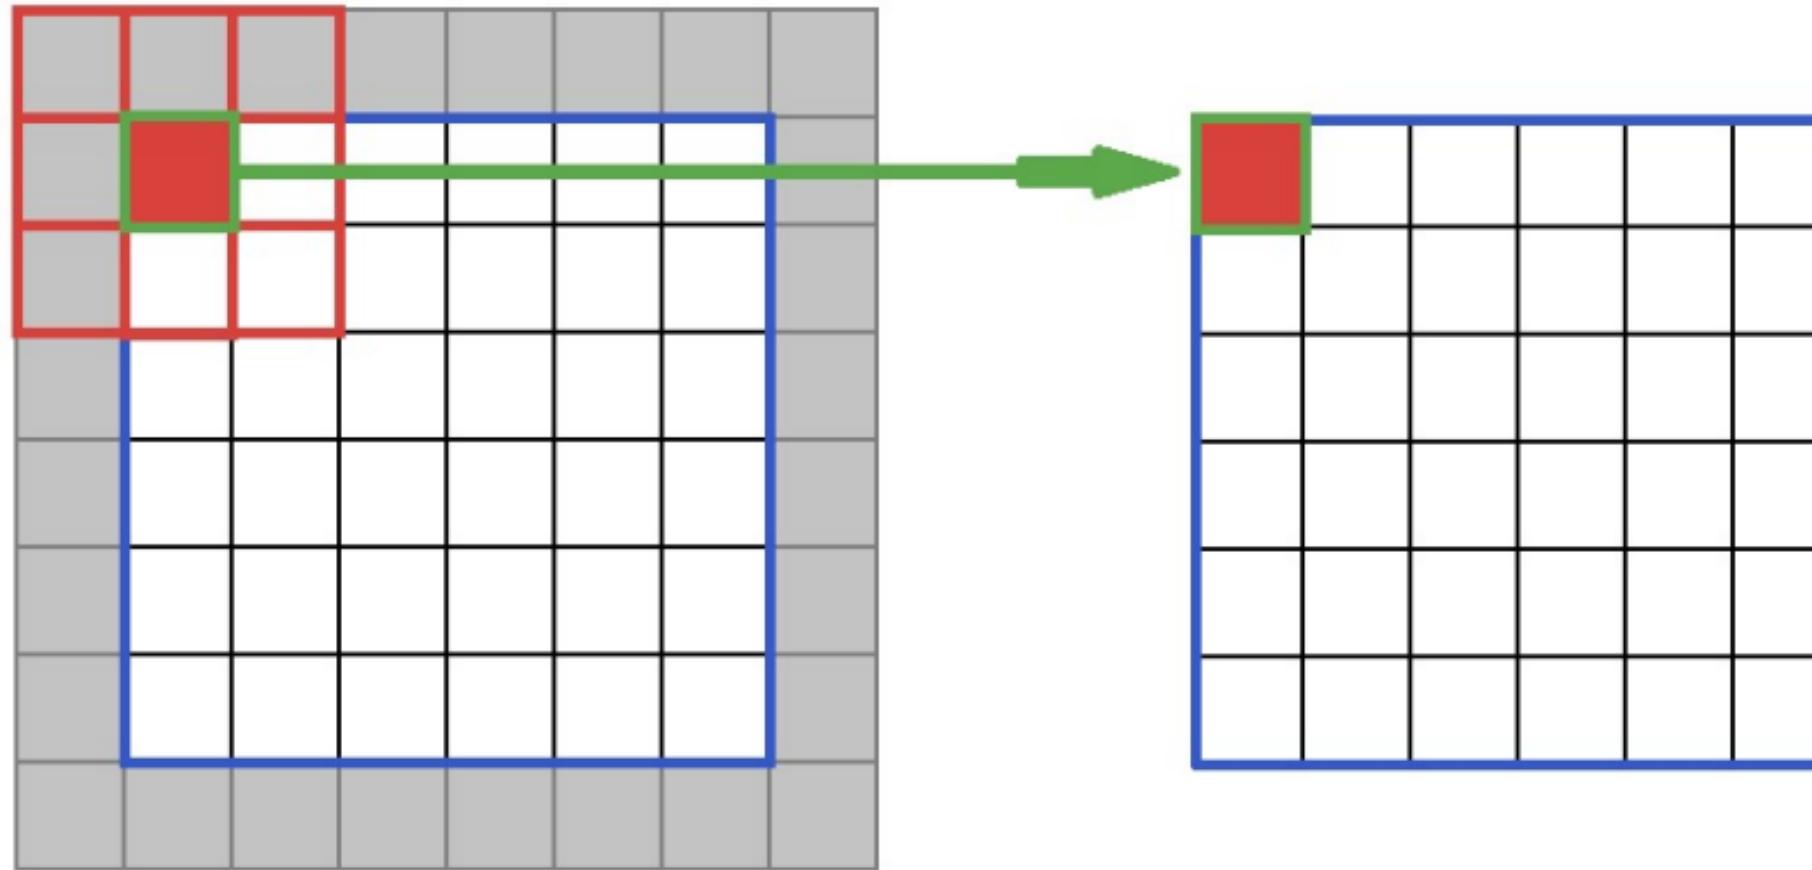

Can then stack a sequence of convolution layers, interspersed with activation functions:

Stacking many convolutional layers leads to identifying patterns in increasingly **larger regions of the input (e.g., pixel) space.**

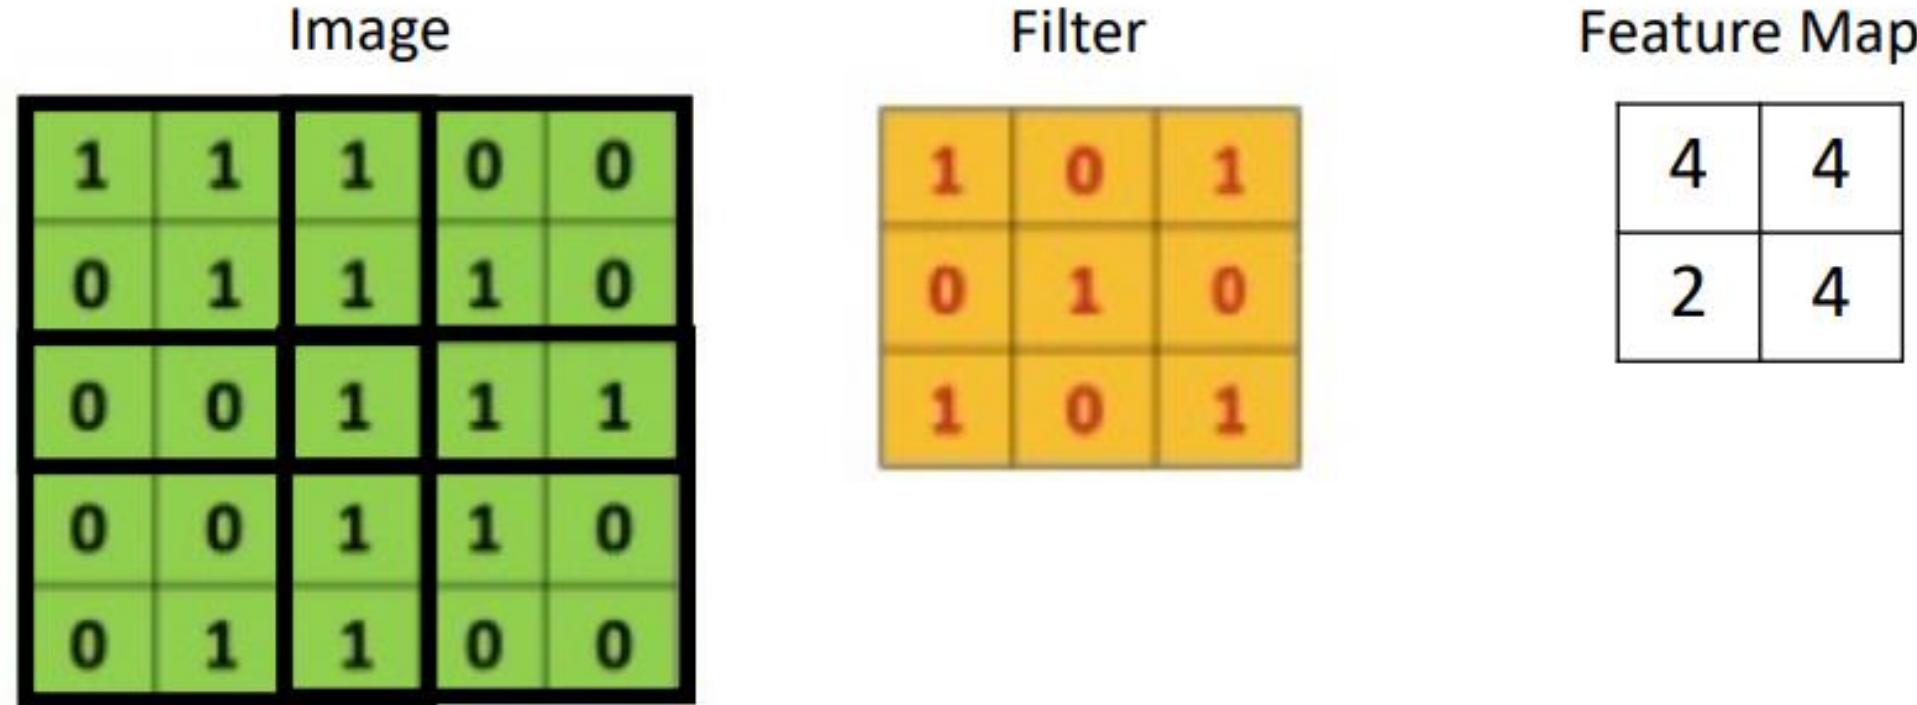

# Convolution: Implementation Details

- **Padding:** add values at the boundaries to control output size

# Convolution: Implementation Details

- **Stride:** how many steps taken spatially before applying a filter
  - e.g., 2x2

# Parameters vs Hyperparameters in Convolutional Layers

- Hyperparameters:

- ?
- ?
- ?

- Parameters:

- ?
- ?

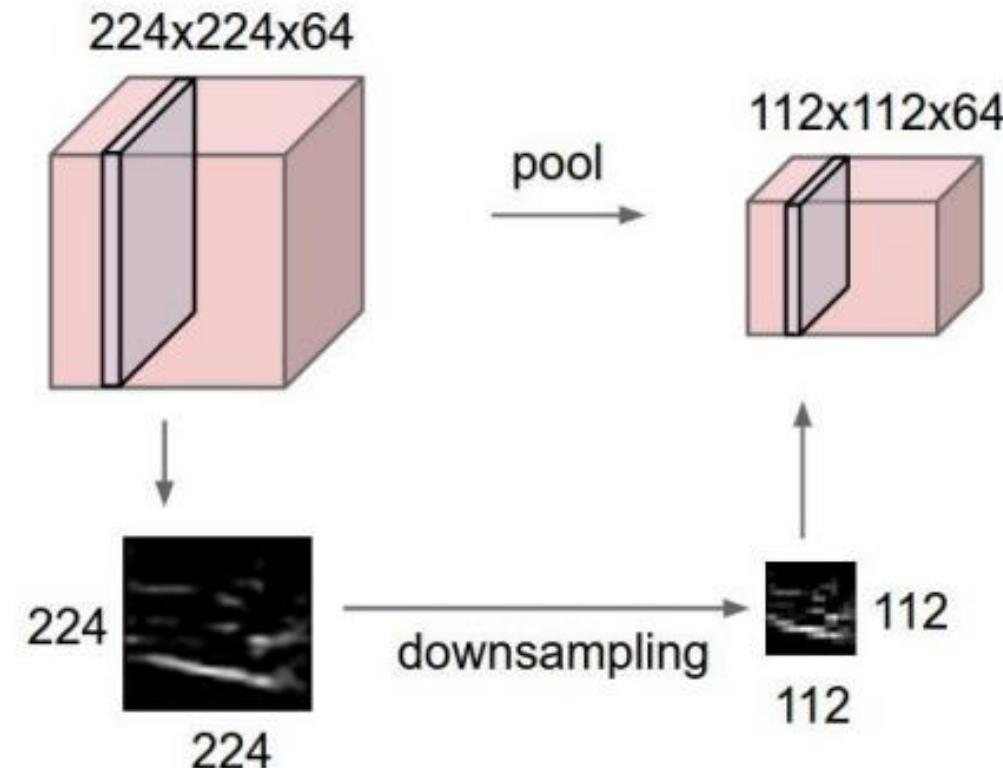

# Parameters vs Hyperparameters in Convolutional Layers

- Hyperparameters:
  - **Number of filters** and their dimensions (**height and width**)
  - **Stride**
  - **Padding type**
- Parameters:
  - **Weights**
  - **Biases**

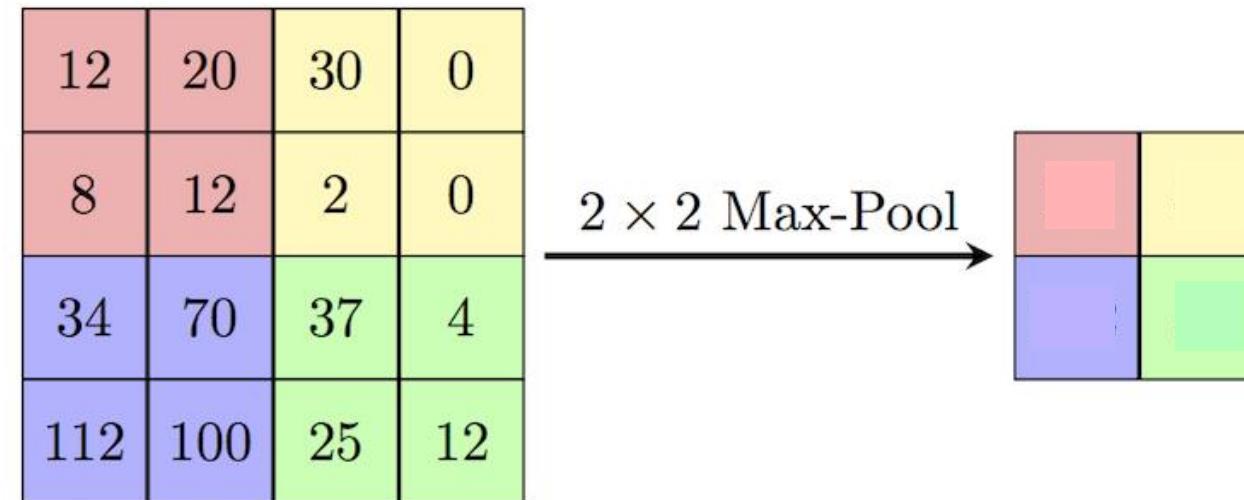

# Pooling Layer

- Makes the representations **smaller and more manageable**
- Helps **retain important information** while discarding unnecessary details.
- Introduces some **invariance to small translations or distortions** (e.g., slight shifts in the image).
- Operates over each activation map independently:

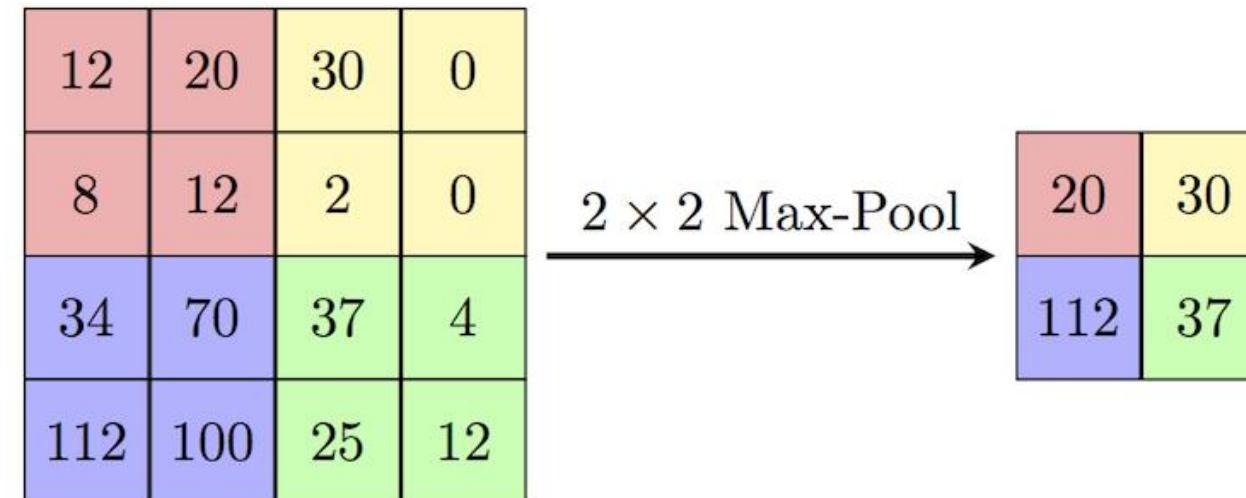

# Types of Pooling

- **Max-pooling:** partitions input into a set of non-overlapping (generally) rectangles and outputs the maximum value for each chunk

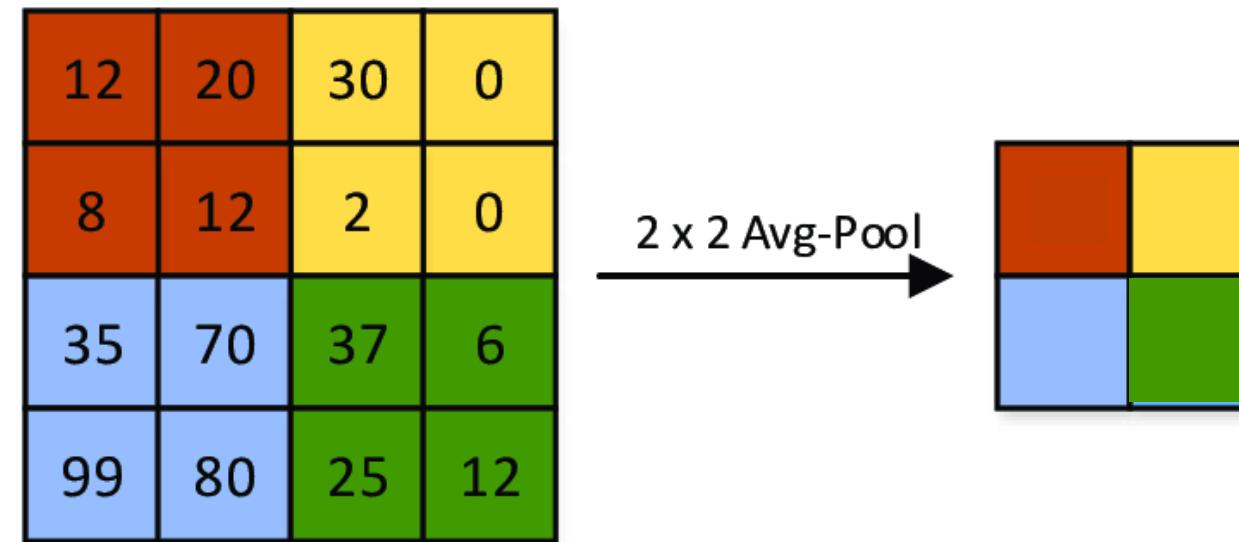

# Types of Pooling

- **Max-pooling:** partitions input into a set of non-overlapping (generally) rectangles and outputs the maximum value for each chunk

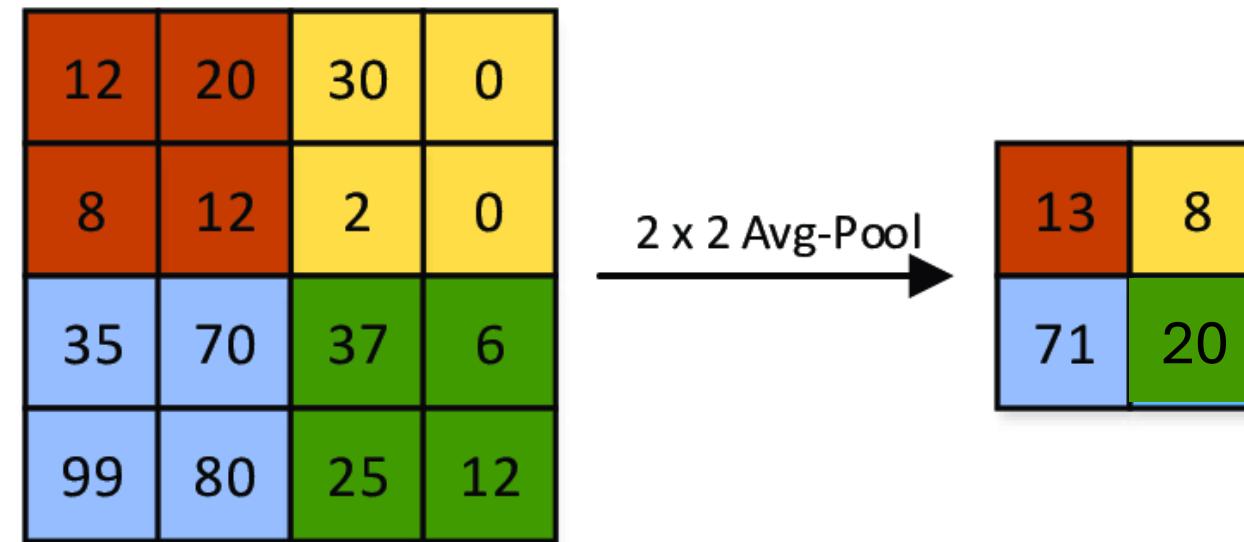

# Types of Pooling

- **Average-pooling:** partitions input into a set of non-overlapping (generaly) rectangles and outputs the average value for each chunk

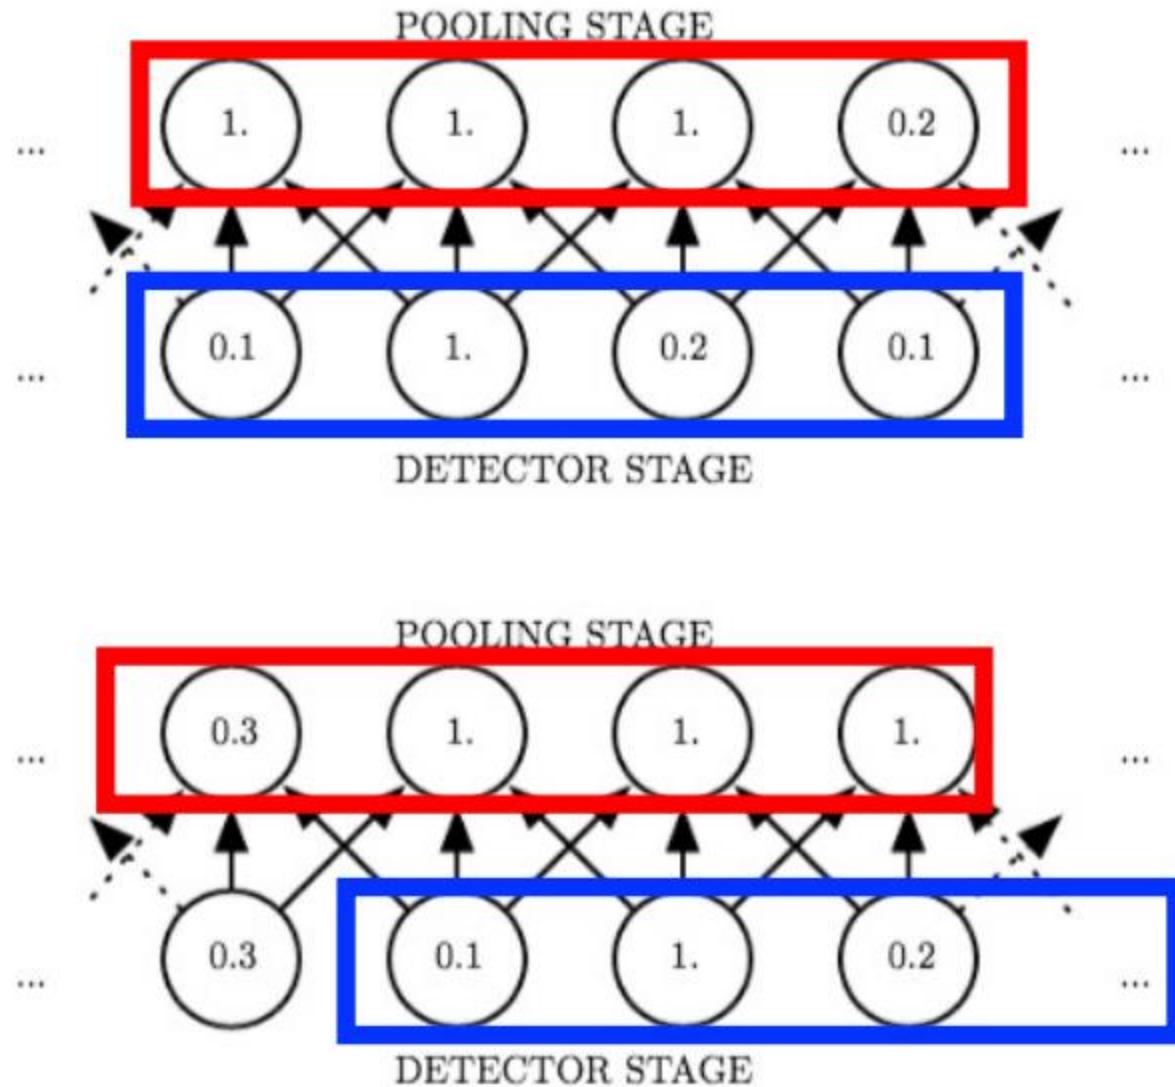

# Types of Pooling

- **Average-pooling:** partitions input into a set of non-overlapping (generaly) rectangles and outputs the average value for each chunk

# Pooling Layer

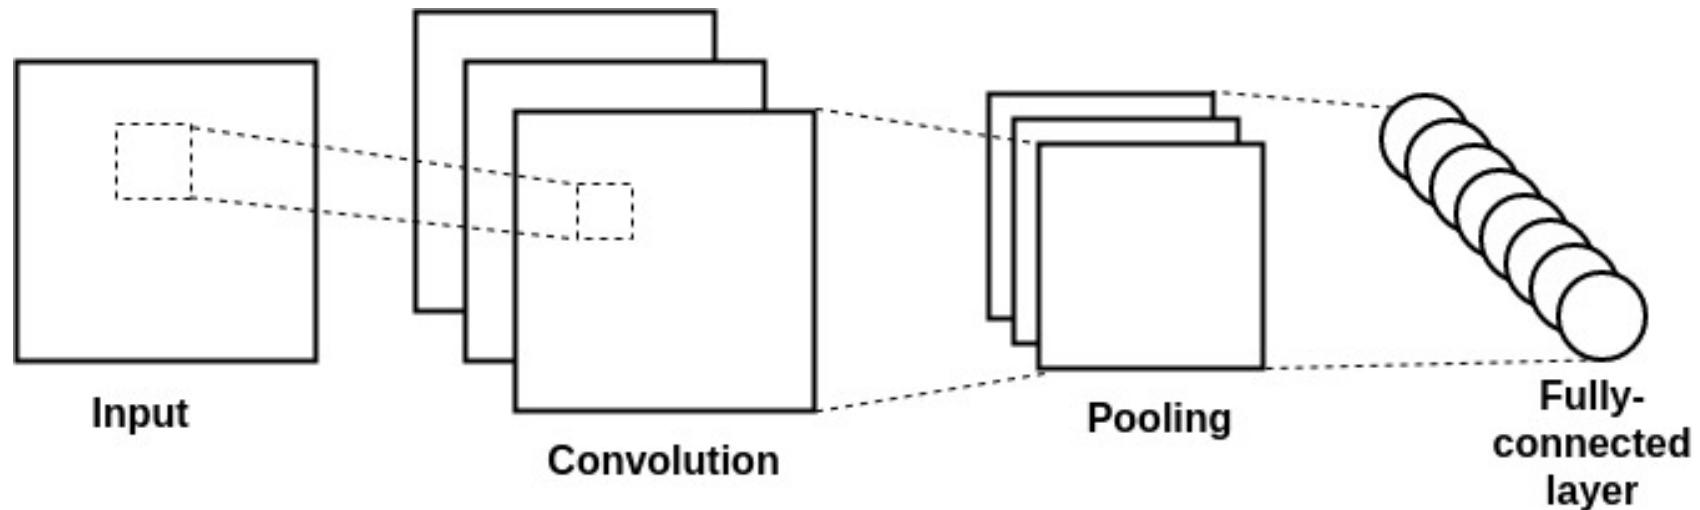

- Resilient to small translations
- e.g.,
  - Input: all values change (shift right)
  - Output: only half the values change

# Pooling Layer: Benefits

- How many parameters must be learned?
  - None
- Benefits?
  - Builds in invariance to translations of the input
  - Reduces memory requirements
  - Reduces computational requirements

# Convolutional Neural Networks

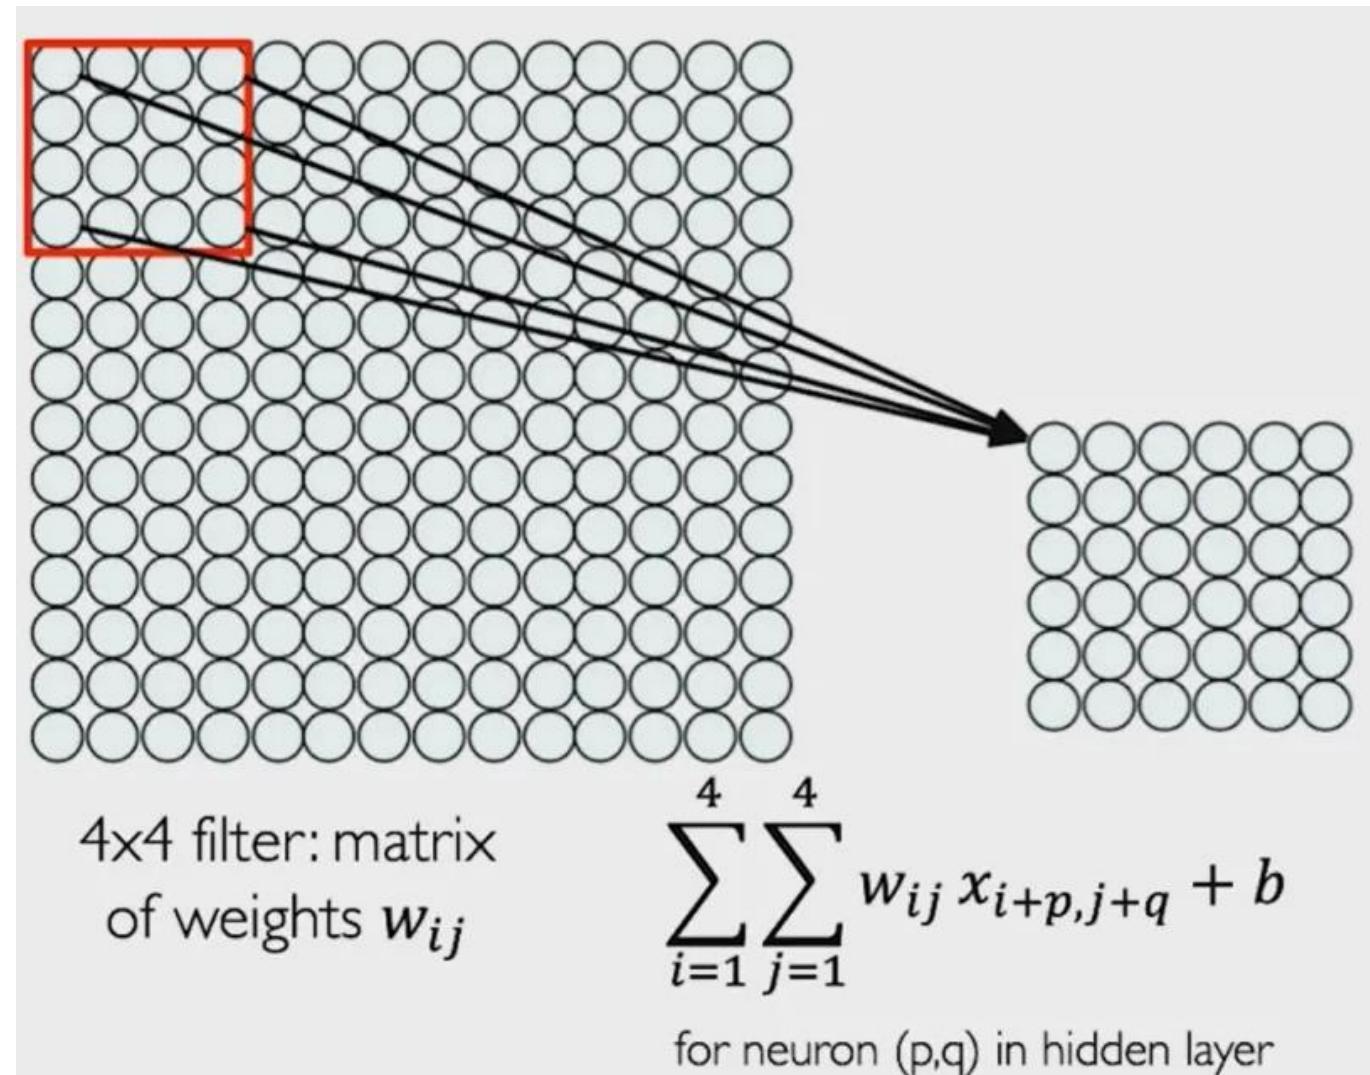

- 1. Convolution:** apply filters to generate feature maps;
- 2. Non-linearity:** Often ReLU;
- 3. Pooling:** Downsampling operation on each feature map.

**Train model with image data.**

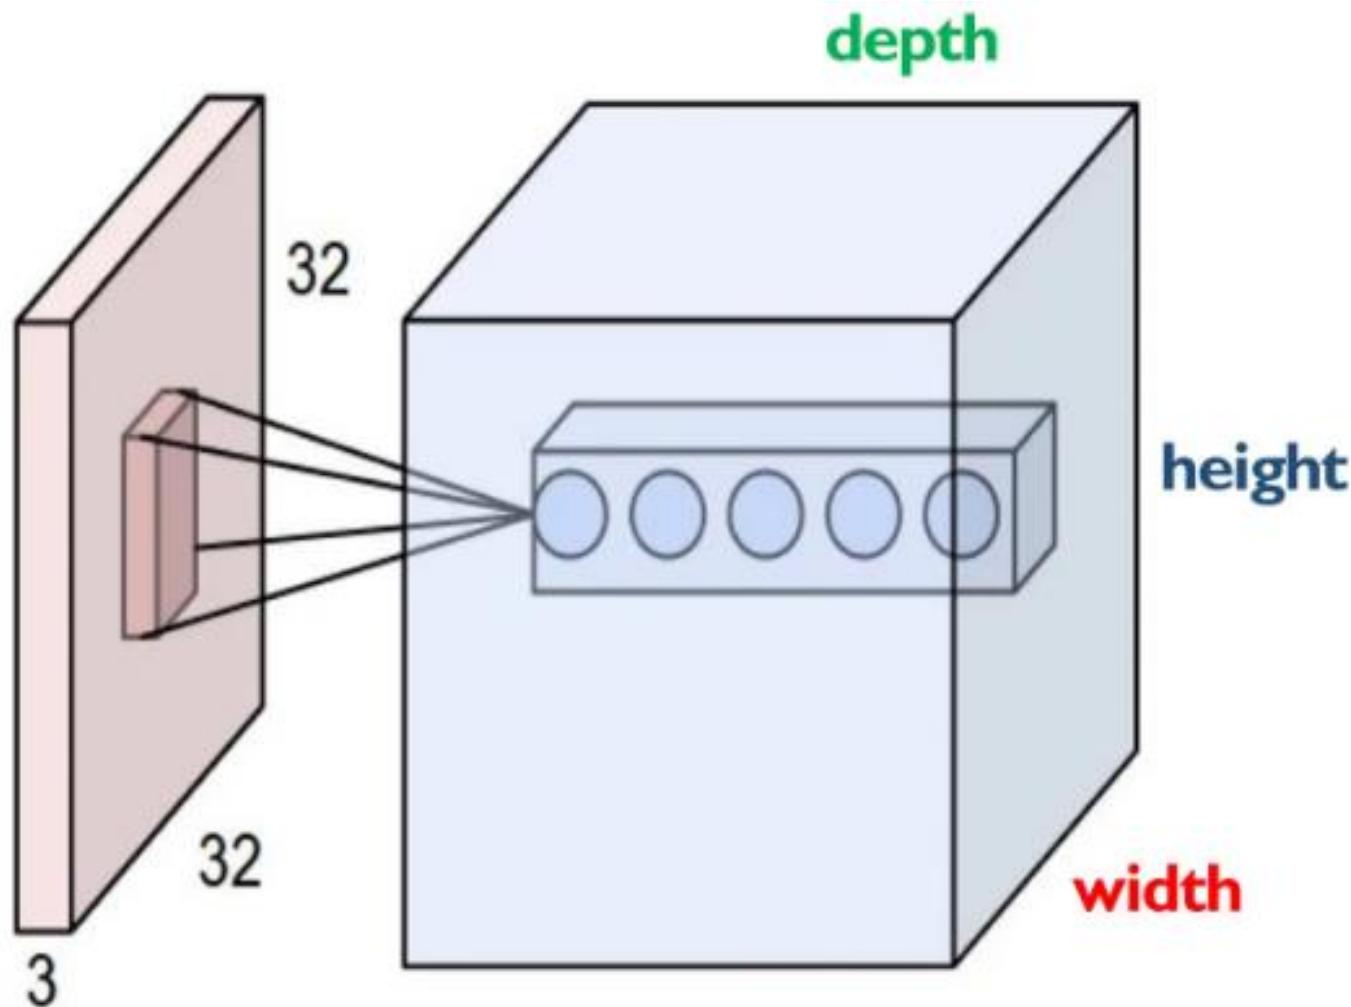

**Learn weights of filters in convolutional layers.**

# Convolutional Neural Networks

- For a neuron in hidden layer:
  - Take inputs from patch
  - Compute weighted sum
  - Apply bias
- Applying a window of weights
- Computing linear combinations
- Activating with non-linear function

# Convolutional Neural Networks

## Layer Dimensions:

$$h \times w \times d$$

where h and w are spatial dimensions  
d (depth) = number of filters

## Stride:

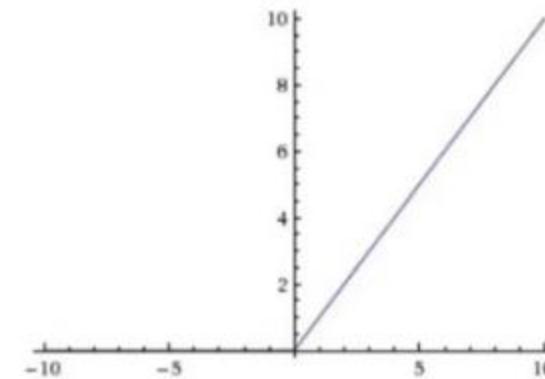

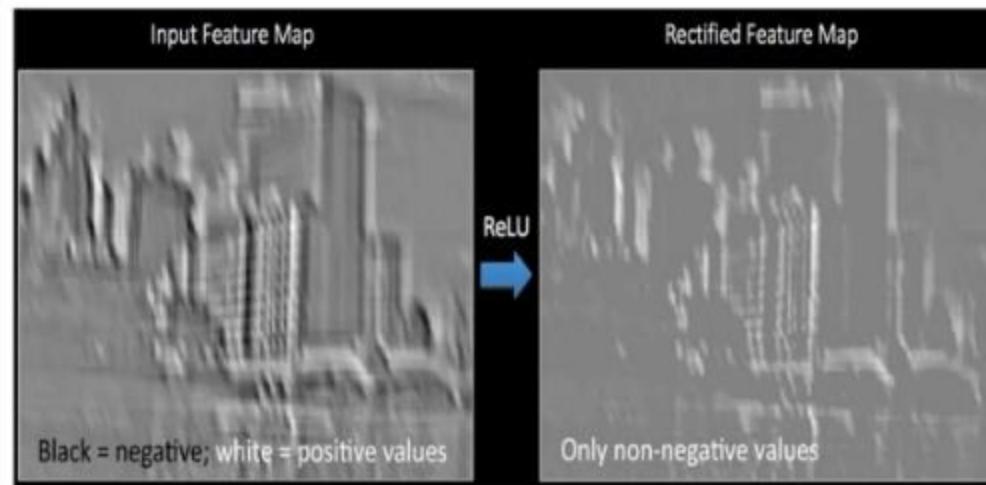

Filter step size

## Receptive Field:

Locations in input image that a node is path connected to

# Convolutional Neural Networks

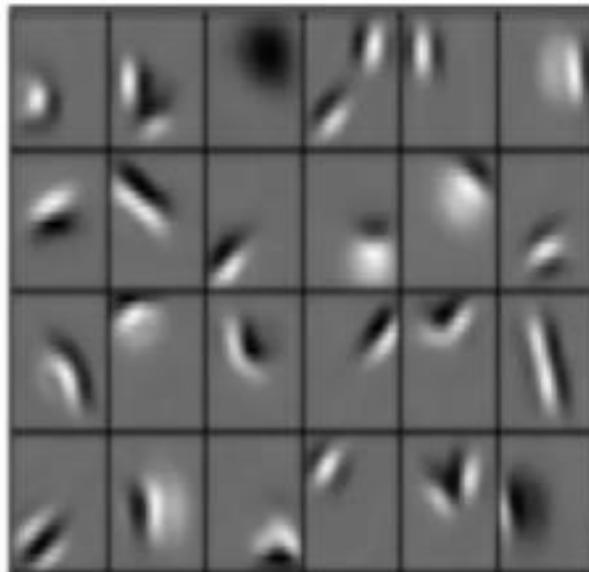

- Introducing non-linearity.
  - Apply after each convolutional layer
  - ReLU: pixel-by-pixel operation that replaces all negative values by zero.
    - Non-linear operation!

$$g(z) = \max(0, z)$$

# Representation Learning in Deep CNNs

Low level features

Edges, dark spots

Conv Layer 1

Mid level features

Eyes, ears, nose

Conv Layer 2

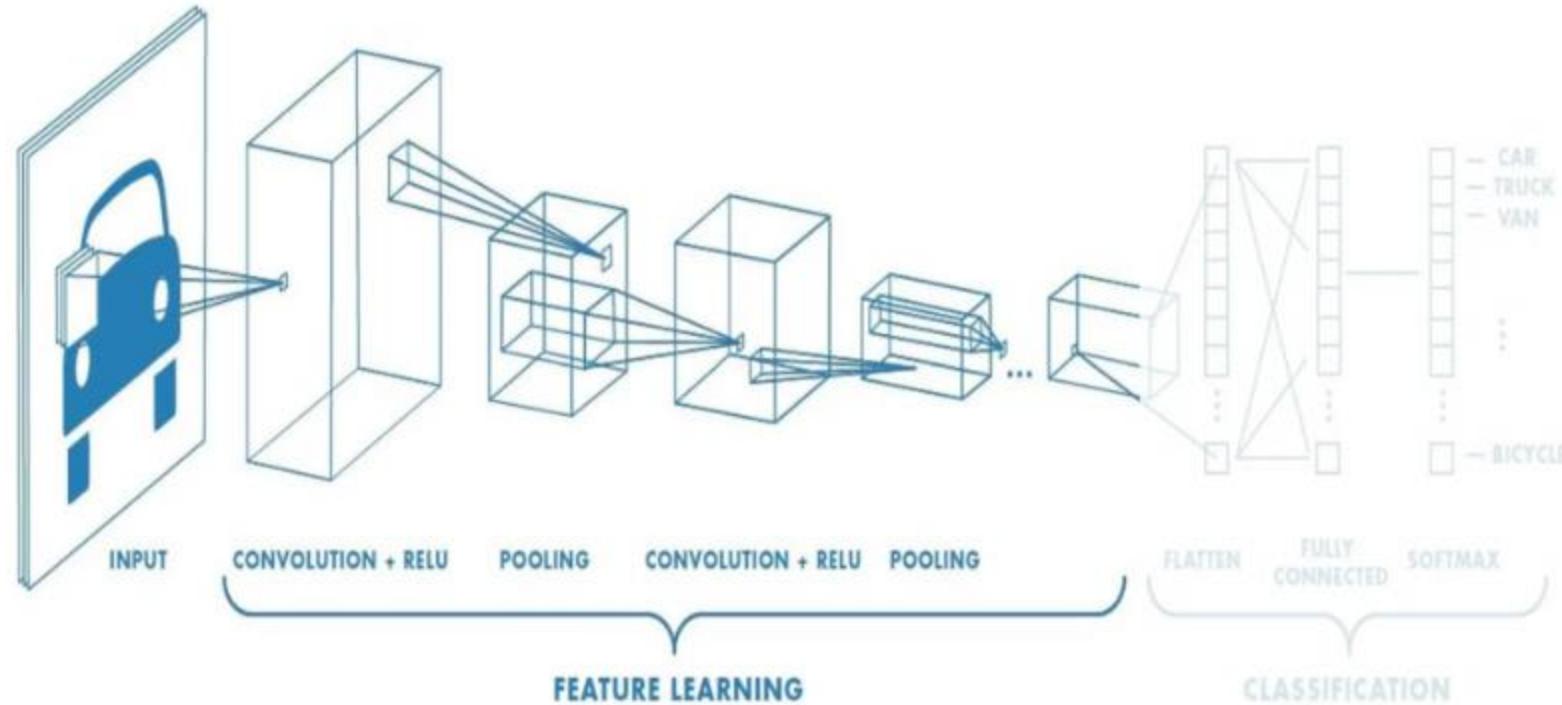

High level features

Facial structure

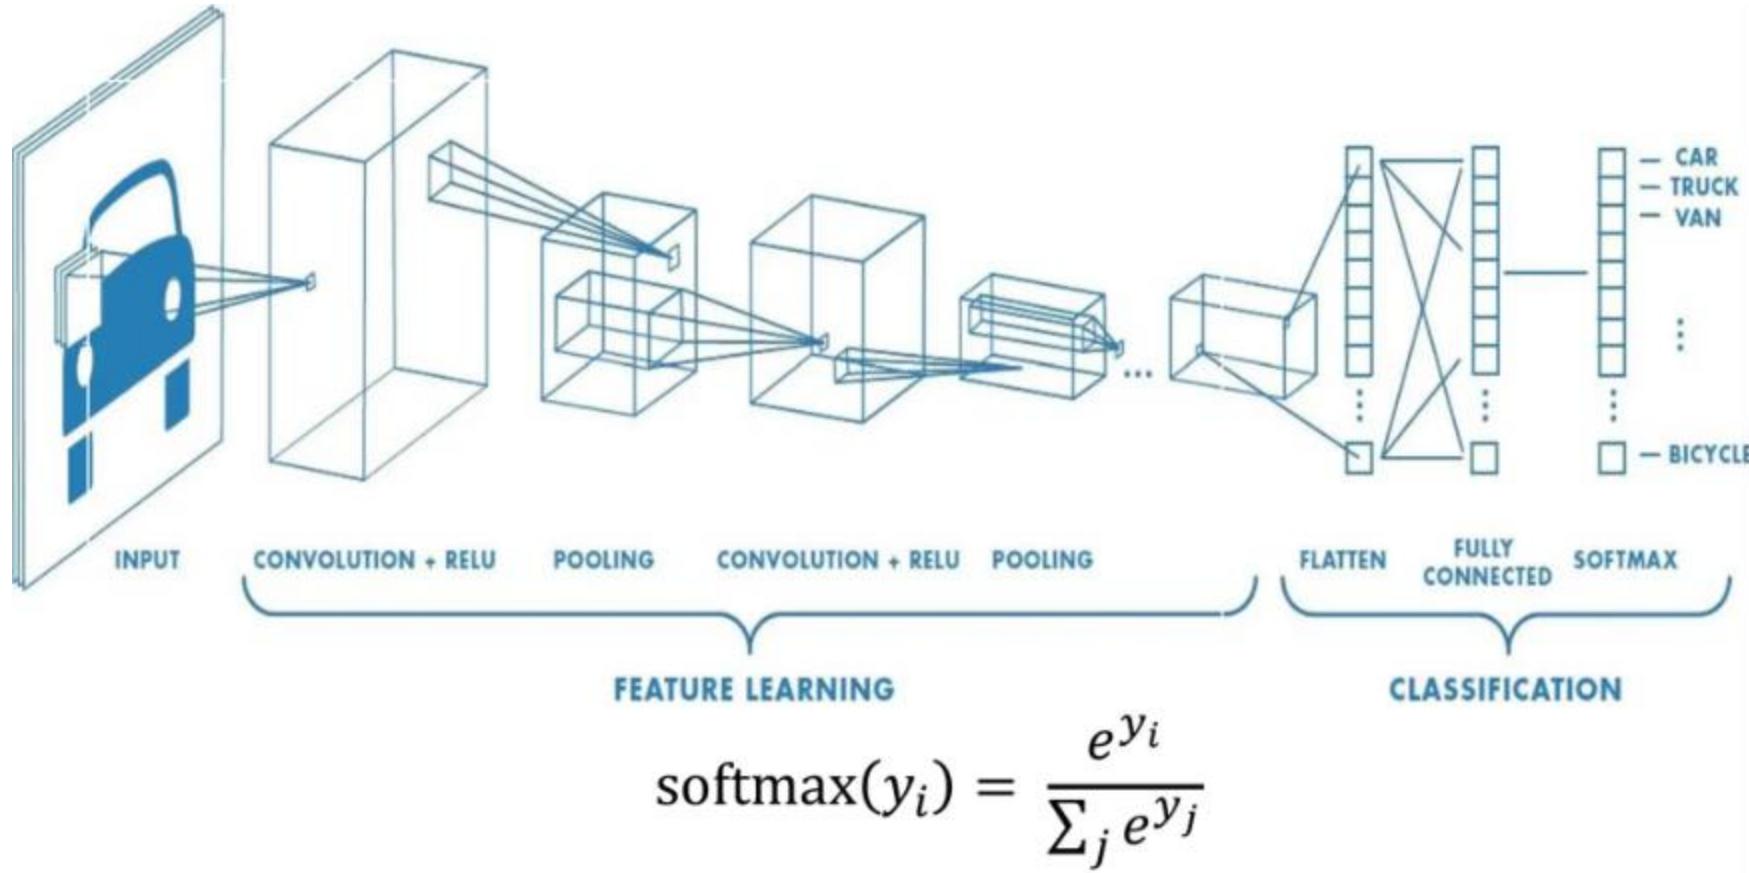

Conv Layer 3

# CNNs for Classification: Feature Learning

1. Learn features in input image through convolution
2. Introduce non-linearity through activation function (real world data is non-linear!)
3. Reduce dimensionality and preserve spatial invariance with pooling

# CNNs for Classification: Predictions

- CONV and POOL layers output high-level features of input
- Fully connected layers use these features for classifying input image
- Express output as probability of image belonging to a particular class
